Rural economics (*X. Cong. Internat. Agr. Gand*, 1913, Sect. 1, pp. [362], table 1).—This section of the report of the Tenth International Congress of Agriculture, devoted to rural economics, has been previously noted editorially (*E. S. R.*, 29, p. 101).

The organization of American agriculture, D. F. HOUSTON (*Amer. Coop. Jour.*, 9 (1913), No. 3, pp. 187-189).—It is pointed out in this address that there is available in the United States 935,000,000 acres of arable land, of which but 400,000,000 is included in farms and improved. The author considers that in fostering industrial centers agriculture has been entirely neglected, and that the United States has come to a point in its history when agriculture must be given the same chance as any other type of production. The greatest undeveloped source of the nation is its people, and the rural population has not had proper development along the lines of education, credit, business organization, sanitation, and social activities.

Marketing of farm produce for greatest profit under present market systems, G. O. VIRTUE (*Ann. Rpt. Nebr. Bd. Agr.*, 1913, pp. 297-306).—The author claims that the cost of marketing may be lessened by reducing the cost of transportation through better country roads and by marketing products in a more finished form and direct to the consumer. It is a question in his mind whether the farmer gains anything by holding his produce for better prices, as he considers that the speculator with his greater knowledge can do this better than the farmer.

A farm-management survey of three representative areas in Indiana, Illinois, and Iowa, E. H. THOMSON and H. M. DIXON (*U. S. Dept. Agr. Bul.* 41, pp. 42, figs. 10).—This bulletin is the result of a survey of 700 farms located in Indiana, Illinois, and Iowa.

Some of the more important conclusions reached were that the average labor income of farm owners was \$408, and of tenants \$370, in addition to the house in which they lived and the farm products used in the home. The landlords received an average of 3.5 per cent on their investment. The tenant's income was in direct proportion to his capital, size of farm, and education. It is stated that modern machinery, with the use of more horses and fewer men, has made the farms of less than 100 acres an inefficient unit. Farms that provide work for the farmer and his sons and permit of the best use of men, horses, and machinery were the most profitable. The yield per acre averaged about 2 per cent higher on farms operated by owners than those operated by tenants. The average labor income of 214 owners having common school education was \$301, and of 186 tenants \$742; of the 46 owners and 51 tenants having high school education \$651 and \$1,268, respectively; and of the 9 owners and 6 tenants having college education \$796 and \$1,721, respectively.

Data are also presented on the sources of farm receipts, distribution of farm expenses, systems of farm tenure, relation of the age of the farmer, etc.

Possible agricultural development in Alaska, L. CHUBBUCK (*U. S. Dept. Agr. Bul. 50, pp. 31, figs. 12*).—The author states that Alaska, with an area of 586,400 square miles, has 100,000 square miles susceptible of agricultural use, 30,000 square miles of which can be tilled. The author presents a summary of available data, including observations made of the south coast and the Yukon drainage areas. He discusses the topography, climate, vegetation, soils, possible agricultural areas, the feasibility of farming in Alaska, grain production, the reindeer industry, cattle and sheep raising, and the difficulties that confront the homesteader. He concludes that, although hardy vegetables, small fruits, and forage crops can be successfully grown over a wide area, and dairying, poultry keeping, and stock raising are promising industries, Alaska's present population does not afford sufficient home market to warrant large agricultural development, in view of the great cost of clearing and preparing the land for tillage. Very little of the available land has been surveyed, and if a survey is made in advance of that made by the Government it is done at the expense of the homesteader.

Farm tenancy in Iowa, B. H. HIBBARD (*Iowa Agr., 14 (1914), No. 5, pp. 242, 243*).—The author points out that in 1880 24 per cent of the farms in Iowa were rented; in 1910, 38 per cent. Grain farming is correlated with a high proportion of tenants, stock farming with a medium proportion, and dairying with a low proportion. Tenancy is high in counties where land is high priced and low where it is cheapest.

York state rural problems, I, L. H. BAILEY (*Albany, N. Y., 1913, pp. 273*).—This book is made up of 25 lectures or summaries of lectures delivered by the author at different places and on different topics. All deal with rural problems. The aim of the book seems to be to present in an impartial way the rural conditions and possibilities.

Rural life in Canada, J. MACDOUGALL (*Toronto, 1913, pp. 248, pls. 24*).—The author, looking at rural life from the religious point of view, calls attention to the depletion of rural population through the decay of village crafts, loss of commerce, and other changes in the modern industrial system. He believes that agriculture has failed to progress as rapidly in scientific business methods as the other industries, and attempts to show the moral effect upon the community that might result from the economic solution of the various rural problems.

The social unrest, according to the author, is due to lack of appreciation for country life, satisfactory laborers, means for social enjoyment, healthful recreation, education for country life, and appreciation of country values and community ideals. He explains the function of the church in rural life, laying emphasis upon social service and preventive work, and notes that rural reconstruction has been most effective where there has been a spiritual awakening accompanying it.

The land.—I, Rural (*London, New York, and Toronto, 1913, vol. 1, 4. ed., pp. LXXXIII+498, pl. 1*).—One of the more important facts noted in this report of the Land Enquiry Committee on the social and economic conditions in the rural parts of Great Britain is that the wages of agricultural workers are not sufficient to house and feed their families properly. The committee recommends that a wage tribunal be formed to fix a minimum wage which shall be sufficient to enable the laborers to live in a state of physical efficiency and to pay a commercial rent for their cottages.

The condition and number of laborers' cottages is also entirely unsatisfactory, resulting in the loss of laborers and a waste of time by the laborers who

remain, since they can not live near enough to their work. The poor housing conditions are responsible for the spread of many contagious diseases and immorality.

Small holdings are deemed desirable because of the greater independence and the relatively greater chance of the laborer rising to a better social position. The committee also considers that small holdings will increase the output and give employment to a larger number of persons per unit of area. To bring this about it is recommended that there should be a land court to fix the price of land, list vacant properties, and encourage the movement in every possible way.

Other means mentioned for improving the condition of agricultural workers are agricultural cooperation, credit, and education.

Rent, wages, and profits of British agriculture (*Economist*, 77 (1913), No. 3666, pp. 1175-1177).—By means of estimates the total output of agricultural products is distributed as follows: Landlords' share £38,500,000, share of the occupiers and their families £51,000,000, and share of wage laborers £30,500,000. The profits of occupiers represent the average income of £100 a year, of which £16 a year is taken from the farm in kind. Out of this income the occupier has to pay his rates, insurance, and replacement of the capital in addition to the personal expenses of his family.

Organization of small rural holdings, J. BENARD (*X. Cong. Internat. Agr. Gand*, 1913, Sect. 1, Ques. 3, pp. 9).—The conclusions reached are that the founding of small holdings would be a means of keeping a man attached to the soil, but that the area of land placed at his disposal must be sufficient to attach him firmly, and that loans granted by the mutual agricultural credit societies for the formation of these holdings will offer a guaranty such that the State could afford to encourage them. The object aimed at in the encouragement of small holdings should be ownership and not tenancy.

Desertion of the rural districts, E. LAUB (*X. Cong. Internat. Agr. Gand*, 1913, Sect. 1, Ques. 2, pp. 66).—The author, after calling attention to the fact that the rural population is becoming a smaller factor in the total population for practically every country, gives as some of the causes for this situation the lower wages in agriculture than in other professions, longer hours of labor, irregularity of employment, and unsatisfactory social position of the agricultural laborer, especially as relates to the large land proprietors. To improve the conditions of the rural working class he recommends the adoption of an agricultural policy favoring the formation of small holdings, improvement of agricultural technique, a campaign against pests of agricultural products, and the extension of the system of insurance.

Agricultural cooperation and rural credit in Europe (*U. S. Senate*, 63. Cong., 1. Sess., Doc. 214, 1913, pp. 916, pl. 1).—This document gives a statement of the information and evidence secured by the American Commission (E. S. R., 28, p. 301) while studying in European countries cooperative land-mortgage banks, cooperative rural credit unions, and similar organizations and institutions devoted to the improvement of rural conditions. It consists principally of speeches or special reports and statements prepared by representatives of the foreign countries for the use of the Commission.

Rural credit and cooperation in Hungary (*Budapest: Roy. Hungarian Min. Agr.*, 1913, pp. 100, pls. 2).—After calling attention to the peoples and agricultural resources of the country and the economic conditions of the farming classes, it is pointed out that because of the conservative tendencies of the Hungarian farmers the government has to take the initial step in practically all new agricultural undertakings. The State furnishes them with seed for sowing, seedling trees, and material for the breeding of live stock. Practically all of

the institutions furnishing agricultural credit had their origin with the State, yet the State does not own a single credit institution of public importance and confines its activities to regulating and supporting them financially.

A description is given of the various types of agricultural credit institutions, showing that the Hungarian Land Mortgage Institute was started to give credit to the large estate owners, and that later the National Small Holdings Land Mortgage Institute arose to furnish small holders with similar credit. The various private and public agencies granting credit to the farmer are noted, the most important being the Hungarian Central Credit Cooperative Society. This organization consists of 2,412 local societies, with 700,000 members, and grants most of its loans to small holders.

The methods employed for the cooperative use of machinery are given. Between 1897 and 1911 the number of dairy unions increased from 34 to 587, and the number of cows belonging to the members increased from 5,937 to over 100,000. A brief discussion of the distributive cooperative societies and the agricultural labor question in that country is included.

Causes and effects of the recent want of success in the department of cooperative agricultural credit in Germany and the lessons to be learned from it, GRABEIN (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel.*, 4 (1913), No. 12, pp. 1-17).—The author concludes that the lessons to be learned from the failure of cooperative credit banks in Germany are that the field of action of the rural loan and savings banks should be limited, not only as regards the granting of credits, but also as regards the credits received. The districts should not be too large. Inasmuch as the purpose of these banks is to satisfy the needs of the country districts for short term loans, loans to large manufacturers and dealers should not be substituted, nor too large a part of the working capital be used for the purchase of real estate on long term loans. At least 30 per cent of the investments should consist of loans repayable before the next harvest. It is also recommended that the loan banks deposit their surplus cash with the central banks and require the central banks to use the most scrupulous diligence in the management of the amounts intrusted to them. Lastly, there should be a rigorous inspection and energetic measures taken to correct any faults at the time of their discovery.

The experience of animal insurance societies in Holland (*Jour. Bd. Agr. [London]*, 20 (1913), No. 7, pp. 628, 629).—A brief financial and statistical account of the cattle, horse, and pig insurance societies of Holland.

Ontario's white coal, F. A. GABY (*Ann. Rpt. Agr. Soc. Ontario*, 13 (1913), pp. 29-34, figs. 5).—The author describes methods of organizing the farmers so that they can obtain electricity from large corporations, to use in farm industries.

Farm efficiency, K. C. LIVERMORE (*Cornell Countryman*, 11 (1914), No. 4, pp. 121-127, figs. 3).—By representing the size, production, diversity, and work rate on an average farm by 100, the efficiency of an individual farm can be obtained by comparisons. The author illustrates his method by comparing 6 farms with the average conditions, pointing out the good and bad features of each farm.

[Agricultural statistics] (*Statist. Abs. Brit. Self-Gov. Dominions [etc.]*, 50 (1898-1912), pp. 310-372).—The acreage and production of the principal farm crops, together with the number of live stock, are given for a series of years for the several British self-governing dominions, crown colonies, possessions, and protectorates. See also a previous note (E. S. R., 27, p. 92).

Agricultural statistics of Austria (*Statist. Rückblicke Osterr.*, 1913, pp. 23-31, 42).—Statistics are given showing the areas devoted to cultivated land, meadows, gardens, pastures, and woods for 1897, and the acreage and harvest

of the principal farm crops for 5 year periods beginning with 1877 and ending with 1912. The number of live stock for various years beginning with 1850 is shown by statistical tables. Statistics are also given showing the production of beer, wine, sugar, and tobacco.

Agricultural statistics of Prussia (*Preuss. Statist., 1911, No. 230, pp. LII+26*).—Data are given showing the area and production of the principal farm crops by Provinces for each year from 1900 to 1911, inclusive.

[**Live stock in Germany**] (*Internat. Inst. Agr. [Rome] Bul. Agr. and Com. Statist., 5 (1914), No. 1, p. 9*).—In 1912 the number of horses was 4,523,059; cattle 20,182,021, of which 10,944,283 were cows and heifers; sheep 5,803,445; swine 21,923,707; goats 3,410,396; and poultry of all kinds 82,702,030.

[**Live stock statistics in the Union of South Africa**] (*Internat. Inst. Agr. [Rome], Bul. Agr. Statist., 4 (1913), No. 12, p. 435*).—Between 1904 and 1911 the number of cattle increased from 3,500,453 to 5,796,949; horses from 449,539 to 719,414; asses from 141,930 to 336,710; sheep from 16,322,503 to 30,656,659; goats from 9,770,545 to 11,762,979; and swine from 679,084 to 1,081,600. Mules decreased from 134,734 to 93,931.

AGRICULTURAL EDUCATION.

Report of the department of agriculture of Sweden, 1911 (*K. Landtbr. Styr. [Sweden] Underdåniga Ber. 1911, pp. [VI]+540+IX*).—This report contains the usual accounts of the various agencies for the promotion of Swedish agriculture, including reports of the work of agricultural, horticultural, dairy, and housekeeping schools, and the dairy, chemical, and seed control stations.

Government aid to agriculture in the Netherlands, 1913 (*Intervention du Govt. en faveur de l'Agriculture dans les Pays-Bas. The Hague: Dir. Agr., 1913, pp. 171, figs. 42*).—A detailed account is given of the organization of the Direction of Agriculture of the Department of Agriculture, Industry, and Commerce, and of government measures for the encouragement of agriculture in general and in special fields, including the agricultural education institutions and courses of all grades, and agricultural experiment stations, fields, and gardens.

Agricultural education (*Ensino Agronomico. Rio de Janeiro: Min. Agr., Indus. e Com., 1911, pp. 87*).—The text is given of a decree of October 20, 1910, together with regulations, establishing a system of agricultural education in Brazil, to include instruction in agriculture, veterinary medicine, zootechny, and rural industries. The agricultural instruction comprises the following: Higher instruction to be given in a higher school of agriculture and veterinary medicine in the federal district in a 4-year course, secondary or theoretical-practical schools of agriculture with 3-year courses, practical schools of agriculture with 3-year courses, agricultural apprentice schools with 2-year courses, elementary agricultural instruction, special schools of agriculture, agricultural home economics schools, special short courses, itinerant agricultural courses, and agricultural conferences and lectures. This instruction is supplemented by experiment stations, experiment and demonstration fields, experiment farms, stations for testing agricultural machinery, and zootechnical and meteorological stations. The object, organization, and equipment of these are outlined.

Horticultural training (*Gartenflora, 62 (1913), Nos. 16, pp. 349-354; 17, pp. 373-383; 19, pp. 413-422*).—These articles include (1) an address by Dr. H. Thiel dealing with general considerations in the organization of instruction in horticultural institutions, (2) an address by H. R. Jung on Horticultural Apprentice and Continuation Instruction, and (3) a discussion of these subjects by leading horticulturists at the second German Horticultural Day in Breslau in July, 1913.

The Seaman A. Knapp school and farm (*Peabody Col. Bul., n. ser., 1 (1913), No. 2, pp. 16*).—This bulletin deals with the scope and character of the work to be undertaken by this school of country life, which it is planned to develop as a clearing house for the rural communities of the South, and a center for the exchange of ideas and information practically tested.

The National School of Streams and Forests, P. GUINIER (*Vie Agr. et Rurale, 2 (1913), No. 35, pp. 224-230, figs. 6*).—In this article the author reviews the history and describes the buildings and equipment, admission requirements, regime, personnel, and curriculum of the National School of Streams and Forests at Nancy in France.

Suggestions for agricultural high schools, P. B. BARKER (*Lincoln, Nebr.: Dept. Pub. Instr., pp. 12*).—These suggestions deal with the division of the high school land into plats for demonstration purposes, soil apparatus, and a list of soil books and soil references for the agricultural library.

The present organization of agricultural high school instruction in Germany, E. FEIGE (*Naturwissenschaften, 1 (1913), No. 40, pp. 958-960*).—The author discusses the present organization of agricultural high school instruction in Germany.

Agricultural instruction in the army, R. HANNE (*Mitt. Deut. Landw. Gesell., 28 (1913), No. 47, pp. 636-642*).—The present status of agricultural instruction in the German army, organized 5 years ago, is discussed in accordance with information obtained from 120 replies to a circular letter of inquiry sent to agricultural instructors and from reports of chambers of agriculture.

Progress in the organization of agricultural instruction in the army and its results in the kingdom, BRANDENBURG (*Mitt. Deut. Landw. Gesell., 28 (1913), No. 27, pp. 393-395*).—The author surveys the present status of agricultural instruction in the army in Germany, and concludes that while opinions as to the value and results of this instruction are not yet everywhere crystallized the efforts that have been put forth have proved correspondingly beneficial.

Agricultural instruction for women in England, MLLÉ. J. MORIN (*Bol. Agr. Téc. y Econ., 5 (1913), No. 57, pp. 823-835*).—An account is given of instruction in gardening and nature study in the elementary and secondary schools of England, the instruction in the colleges of horticulture for women at Studley and Swanley, and the agricultural instruction in the University College of Reading.

French itinerant schools of agricultural home economics, A. DUCLOUX (*Vie Agr. et Rurale, 2 (1913), Nos. 32, pp. 149-150; 38, pp. 305-308; 43, pp. 438-440, figs. 3*).—The author gives an account of the history, curriculum, present status, results, and future of itinerant schools of home economics in France.

Farm women's institutes in America (*Dept. Agr. and Tech. Instr. Ireland Jour., 14 (1913), No. 1, pp. 31-40*).—An account is given of the organization and aims of the farm women's movement in Canada and the United States.

Women's institutes in Ontario, 1913 (*Rpt. Women's Insts. Ontario, 1913, pt. 1, pp. 120*).—This report contains the proceedings of the annual convention held in November, 1912, together with a few selected papers, statistics for the year ending with May, 1913, and list of officers for 1912-13.

Farmers' institutes of Ontario, 1913-14 (*Rpt. Farmers' Insts. Ontario, 1913, pt. 2, pp. 51*).—This report contains announcements of meetings for the winter session of 1913-14, and a statistical statement of the local farmers' institutes throughout the Province for the year ended May 31, 1913.

North Wales egg and poultry demonstration train, April 23 to May 6, 1913, E. BROWN (*Jour. Agr. Organ. Soc., 7 (1913), No. 3-4, pp. 83-94*).—The organization, equipment, staff, etc., of the train are outlined.

A plan for a rural community center, A. R. MANN (*Cornell Col. Agr. Ext. Circ. 1, 1913, pp. 16, figs. 7*).—This circular shows how a rural community center may be developed in the open country, village, and the smaller town and city. Under the plan proposed a piece of land about 20 to 30 acres in extent is laid out in somewhat the same way as the usual fair grounds, but to be used as a public park and to be open at all times, also a grove for picnics, summer gatherings, and shelter purposes, a consolidated or combined elementary and high school building in or near the grove, athletic grounds, experiment or demonstration plats, and a building that can be heated for year-around meetings and exhibits.

Farmers' clubs, A. D. WILSON (*Univ. Minn., Dept. Agr., Ext. Bul. 46, 1913, pp. 8, figs. 5*).—This bulletin sets forth in a simple way some of the things that farmers' clubs are doing for communities in which they exist and some of the things they may do, and points out the steps necessary for organizing and conducting a farmers' club.

Addresses given at the Rural Life Conference, Middlebury College, July 7-13, 1913, with rural life bibliography, R. McFARLAND (*Middlebury, Vt., 1913, pp. 48*).—The papers presented at this conference included, among others, The Importance of the Rural Problem, by R. J. Sprague; Marketing of Farm Products, by E. S. Brigham; Rural School Improvement, by J. M. Thomas; New Activities in Rural Education, by F. E. Howard; Rural Libraries, by Rebecca W. Wright; Play and Athletics for Rural Vermont, by L. A. Morhous; and The Work of the Grange, by W. N. Cady.

Materials and methods in high school agriculture, W. G. HUMMEL and BERTHA R. HUMMEL (*New York, 1913, pp. XI+385, pls. 22*).—This book has been prepared to meet the needs of persons interested in the introduction or in the teaching of agriculture in high schools, towns, cities, or rural communities where large numbers of students are drawn from the farming population.

In addition to outlining the agricultural course as a whole for the high schools of the type mentioned, the book gives helpful suggestions as to the selection of suitable materials, teaching methods, and equipment for the various subjects of the course. Practicums and references for collateral reading follow each chapter.

Nature study lessons (*Cornell Rural School Leaflet, 7 (1913), No. 2, pp. 213-240, figs. 17*).—This leaflet contains suggestions on Corn Day in the school, and lessons on cows, trees, and birds.

Principles and practice of school gardening, A. LOGAN (*London, 1913, pp. XV+313, pl. 1, figs. 102*).—In this text-book, intended as a guide for teachers and pupils in school gardening, the author has included the matter which after 5 years of experience in teaching the subject, he considers to be most usable from an educational point of view and most essential from the standpoint of horticulture and rural science. The method of presentation adopted, which has been found suitable in dealing with pupils between 12 and 16 years of age, is mainly experimental and practical. "While the text of the volume aims at the analysis of operations with a view to the examination of the laws of nature upon which each is based," the exercise appended to each chapter for the purpose of correlating school gardening with other subjects in the curriculum, encourage the student to extend his intellectual horizon, to regard these operations in their world relation, etc.

Suggestions for household exhibits (*Iowa State Col. Agr. Ext. Dept., Home Econ. Circ. 4, 1913-14, pp. 8, pl. 1*).—Suggestions are made for the arrangement of exhibits of household materials, and score cards are given for use in judging homemade food products and needlework and other textiles.

NOTES.

Idaho University.—Press reports announce that Dr. Melvin A. Brannon, dean of the college of liberal arts at the University of North Dakota since 1911, has been appointed president.

Illinois University.—A traveling school of fruit growing was conducted from February 2 to February 21 by the division of pomology, in cooperation with the Southern Railway.

Louisiana University.—A high school rally will be held on May 1 and 2 at which contests will be held in forestry, domestic science, corn and live stock judging, etc. Each contestant is to pay an entry fee of \$1, the fund thus collected being used for reducing the railway expenses of the more distant schools.

Montana College.—The registration at the annual farmer's week showed an increase of 60 per cent over the previous year and a total of 275 students. There were about 25 speakers in addition to the members of the college faculty.

Nebraska Station.—H. A. McComb, a 1902 graduate of the university, has been appointed assistant in horticulture at the North Platte substation beginning February 15.

Cornell University.—The landscape art building is being occupied and the contract has been let for the new agronomy building. A new greenhouse, 34 by 40 feet, has been completed for use in vegetable gardening and will form the beginning of a range to include from 12,000 to 15,000 square feet of space.

The total registration for the various farmer's week programs was 2,569 and the total attendance is estimated at about 3,500. Nearly 400 lectures and demonstrations were given and 16 conferences and conventions were held.

The department of pomology has leased a tract of 8 acres of land near Fort Byron for experiments in orchard renewal.

Vermont University.—The extension service is organizing 5-day extension schools of agriculture, arrangements having been completed for about 10 of these schools. The first of these was held in South Barre with an average daily attendance of 54.

Virginia Station.—The state legislature has increased its annual appropriation to the station from \$10,000 to \$16,000. The State Board of Agriculture has also increased its allotment for station work to \$7,500 annually, this money being derived from the fertilizer tag tax, and the work being conducted under the direction of the station. These funds are used to conduct experiments with farm crops and fruit and in soil fertility investigations elsewhere than at Blacksburg, 12 counties now being represented. The additional amounts will be used to study problems in peanut and cotton culture in Nansemond County and to begin soil fertility and crop rotation tests in Culpeper County.

Virginia Truck Station.—H. S. Garrison resigned February 1 as superintendent of the Tasley substation to accept a position with the Bureau of Plant Industry of this Department.

Washington College and Station.—At a recent meeting of the board of regents, there was organized a department of dry-land demonstration and experiment

for work in the semiarid portion of the State. It is proposed that the members of the staff advise and assist farmers in that section, giving attention to demonstration work connected with the production of crops adapted thereto and other problems bearing on dry-land agriculture. In order that the work of the department may be as closely correlated as possible with that of the station and the State Bureau of Farm Development, the director of the station has been made director of the department. H. E. Goldsworthy, a graduate of the college, who has had considerable experience in dry-land farming in Alberta, has been appointed vice-director with headquarters at Lind.

Byron Hunter, formerly of the Office of Farm Management of this Department, has been appointed vice-director of the Bureau of Farm Development, the director of the station being its director. This bureau has charge of the county agricultural work in the State in cooperation with this Department.

William D. Foster, for a number of years superintendent of the college farm, died January 25.

Wisconsin University and Station.—H. E. Lothe, D. V. M., has been appointed instructor in veterinary science in the college of agriculture and assistant in veterinary science in the station. M. H. Crissey has been appointed assistant in agricultural economics and executive secretary in the college and station.

Agricultural Education in Canada.—At the request of the minister of education, Queen's University, Kingston, has established the new degree of bachelor of science in agriculture. The course covers four years, of which the first two are to be spent in residence at the university and the remaining two at the Ontario Agricultural College. In order to increase their knowledge of practical agriculture, candidates for the degree will be expected to work during the summer vacation between the third and fourth years of the course, either on the farm of the agricultural college or on some other approved farm. At the end of each of the two years taken at the agricultural college the government will give a scholarship of \$100 to each candidate recommended by the president of the college.

The department of education will accept the degree of B. S. Agr. as the academic qualification for a specialist's certificate in both science and agriculture and for a public school inspector's certificate. The former certificate will be granted after a year's professional training at the faculty of education of either Queen's University or the University of Toronto. The holder will be regarded as qualified to teach both science and agriculture in a high school, continuation school, or collegiate institute, and each county representative, in addition to his usual duties, will conduct under the school board concerned, classes for farmers and farmers' sons throughout the county.

It is announced that as soon as the new class of specialists is available, the government will also make liberal grants for maintenance and increase of teachers' salaries for the encouragement of secondary school classes in agriculture. The payments to the teachers, however, will obligate the teacher to teach at least two years in the Province of Ontario.

The new buildings of the Manitoba Agricultural College, located on a site of 1.100 acres just south of Winnipeg, were sufficiently completed to permit of their use in the fall of 1913. The group as a whole will cost \$5,000,000 and will require from 2 to 3 years additional for its completion.

The new college of agriculture of Saskatchewan University is offering a 4-year course leading to the degree of B. S. in Agr., and a 3-year course leading to the certificate of Associate in Agr. The first class in agriculture, consisting of 65 students, entered last fall, nearly all of whom matriculated in the 3-year course.

The Province of Alberta is undertaking a new form of instruction in Canada in opening 3 schools of agriculture, viz, at Claresholm, with W. J. Stephens,

principal, to cover southern Alberta and deal with education best suited under dry farming and irrigation conditions; at Olds, with W. J. Elliott, principal, which will look after the interests of central Alberta where the soil is a heavy black loam; and at Vermilion, with A. E. Howes, principal, to deal with northern conditions. Tuition in these schools will be free and the 2-year course will approximate very closely to the first 2 years of the regular agricultural college course for the degree of B. S. in Agr. Domestic science courses will also be offered. In addition to the principal there will be at least two professors at each school whose time during the summer will be devoted to extension work and getting in touch with the farm homes. The schools will be operated under a board composed of a body of practical farmers.

An act has been passed providing for the establishment of agricultural schools at such places in the Province of New Brunswick as may be decided upon by the Lieutenant-Governor-in-Council, who is also authorized to purchase such lands and erect such buildings as he may deem necessary for the purpose. The curriculum of the schools will include agriculture, horticulture, forestry, care and management of farm animals, butter and cheese making, manual training, and kindred subjects, as well as the elements of sciences bearing on these subjects. The schools will be largely under the management of the New Brunswick department of agriculture, which will regulate the conditions of admission, fix tuition fees, arrange courses of study, supervise the conduct and work of students, grant certificates of proficiency or other awards, etc. The Lieutenant-Governor will appoint the staffs of the schools and authorize the expenditures to be made by the department of agriculture for these schools.

The Province of Prince Edward Island has provided a summer school of agriculture and nature study for the teachers in its rural schools. The courses are given in the building of the Prince of Wales College at Charlottetown, and are of two weeks' duration. An attendance of over 250 was enrolled in 1913, out of a total of 590 teachers on the Island. The traveling expenses and a portion of the living expenses of these students were borne by the Province.

New Journals.—*The American Journal of Tropical Diseases and Preventive Medicine* is being published monthly at New Orleans as the official organ of the American Society of Tropical Medicine. The initial number contains, among other original articles, an account of The Species of Anophelines Concerned in the Transmission of Human Malaria by F. Knab, and one On the Adult Forms of *Trypanosoma americanum* in Naturally Infected Animals by F. M. Johns. It also contains reviews, notes, etc.

The Indian Journal of Medical Research is being published quarterly as the official organ of the Indian Research Fund Association. It is to contain original papers and notes on various topics directly or indirectly connected with medical and sanitary science, including hygiene, sanitary engineering, sanitary laws, statistics, bacteriology, parasitology, entomology, etc. Several of the articles in the initial number are of particular interest to entomologists.

The Canadian Department of Agriculture is publishing the *Agricultural Gazette of Canada* with J. B. Spencer as editor. This will be the official organ of the department and will be issued monthly in both English and French editions. The initial number contains an account of the department and its work, the text and other data regarding the agricultural instruction act of June 6, 1913, short accounts of the various provincial departments of agriculture, statistics as to the attendance of students in agriculture and veterinary courses for the current year, etc.

Boletim do Ministerio da Agricultura, Industria, e Commercio is being published at Rio de Janeiro and will contain official announcements of the Brazilian

Government relating to agriculture, memoirs and original articles, translations, reprints, statistics, and notices relating to both Brazilian and foreign agriculture. The ministry is also issuing a monthly entitled *Superintendencia da Defesa da Borracha*, which contains announcements, statistics, notes, and related matter of interest to the rubber industry.

The American Home Economics Association has established in the *Journal of Home Economics* a Housekeepers' Department. This is designed to bring to the housekeeper's attention progress made in the laboratory and elsewhere in matters pertaining to food and other home problems, and to interpret for her guidance the results of research.

A quarterly *Journal of the American Society of Agronomy* has replaced the annual *Proceedings* of the Society. It will contain technical papers of some length, brief articles, and personal and scientific notes and news items.

The Veterinary Alumni Quarterly is being published by the Veterinary Alumni Association of the Ohio State University. The initial numbers contain several original articles along veterinary lines.

The Mississippi Agricultural Student is a new quarterly devoted to the advancement of agricultural education, and published by the School of Agriculture of the Mississippi College.

The British Ecological Society has established *The Journal of Ecology* as its official organ, to include general articles, reviews of current work, notes, bibliographies, etc.

Mitteilungen der Landwirtschaftlichen Lehrkanzeln der k. k. Hochschule für Bodenkultur is being published in Vienna, and contains original articles from this and other institutions.

Zeitschrift für Pflanzenzüchtung, a joint organ of the German and Austrian Societies for the Promotion of Plant Breeding, is being published in Berlin. It contains original articles, abstracts, notes, etc.

Miscellaneous.—A large bequest, stated at \$1,250,000, is announced in the will of the late W. Gibson of London and Belfast to institute a scheme for providing sons of farmers in Down and Antrim counties, Ireland, with educational advantages. No further details are as yet available.

Dr. G. Rubland, secretary of the International Agricultural Union, and well known for his writings on agricultural economics, notably those relating to the marketing of cereals and agricultural credit, died January 5 at the age of 54 years.

Julius Lenkowsch, author of the well-known treatise on Chemical Technology and Analysis of Oils, Fats, and Waxes and other works died September 16, 1913, at the age of 56 years.

Science announces a gift of \$30,000 by Mrs. Russell Sage to the Joseph Slocum Agricultural College of Syracuse University.

L. G. Sutton has contributed \$5,000 toward the fund for buildings and laboratories for agricultural and other departments at University College, Reading.

CONTENTS OF VOL, XXX, NO. 6.

	Page.
Recent work in agricultural science.....	501
Notes.....	600

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

An investigation of phytin, Plimmer and Page.....	501
The constitution of the luteins, Serono.....	501
Methods for preparation and determination of cholesterol, Hepburn.....	501
Synthesis of glucosids from glycerol and glycol, Bourquelot and Bridel.....	502
On the nature of the sugars found in the tubers of arrowhead, Miyake.....	502
The starch content of cassava roots, De Jong.....	502
Chemical nature of the "tannin masses" in the fruit of the persimmon, Clark..	502
The occurrence of barium in tobacco and other plants, McHargue.....	502
About a hemagglutinin in the Euphorbia, von Eisler and von Portheim.....	503
Enzymatic cleavage of hippuric acid by mold fungi, Dox and Neidig.....	503
Cleavage of pyromucuric acid by mold enzymes, Dox and Neidig.....	503
Enzymes of washed zymyn and dried yeast: I, Carboxylase, Harden.....	504
Did von Wittich antedate Ostwald in the definition of enzym action? Berg..	504
Precipitation of enzymes by aluminum hydroxid, Welker and Marshall.....	504
Precipitation of colloids by means of aluminum hydroxid, Marshall and Welker.	504
Direct determination of elementary nitrogen with calcium carbid, Natus.....	504
A micro-Kjeldahl apparatus, Morse.....	505
An apparatus for the absorption of fumes, Folin and Denis.....	505

A modification of a method for examining fermentation gases, Frieber.....	505
The volumetric determination of manganese, Metzger and Marrs.....	505
Error of analysis and nitrogen economy of arable soils, Pfeiffer and Blanck....	505
Note on the volatility of sulphuric acid when used in vacuum drying, Gore...	505
Direct determination of moisture in foods by distillation, Michel.....	505
A special flask for the rapid determination of water in flour and meal, Cox...	506
Determination of moisture in maize for export, Vipond.....	506
Contribution to the study of flour, Gury.....	506
Determination of water with Hoffman's apparatus, von Haydin.....	507
Investigations in regard to varieties of egg yolk, Emmerich.....	507
A new instrument for measuring strength of alcoholic liquids.....	508
An attempt to estimate the vitamin fraction in milk, Funk.....	508
Aluminum hydroxid as a protein precipitant in milk, Welker and Marsh....	508
Adulteration of milk.—Watering, Porcher.....	508
A rapid method for determining the addition of water to buttermilk, Höyberg..	508
A rapid method of determining the solids in evaporated milk, Hunziker.....	509
Studies on flax retting, Tadokoro.....	509
Progress made in the manufacture of beet sugar in 1912, von Lippmann.....	510

METEOROLOGY—WATER.

Reports on agricultural meteorology.....	510
Agricultural meteorology, Yranzo.....	510
Making weather forecasts more useful in the open country, Vanderlinden....	510
Report of the Iowa Weather and Crop Service for 1912, Chappel.....	510
Division of meteorology, Helme.....	510
English climate and some of its variations, Marriott.....	510
Climate and meteorology of Australia.....	511
The station of agricultural meteorology at Riudabella (Tarragon), Spain, Gil...	511
The rains of the Nile Basin and the Nile flood of 1911, Craig.....	511
Protection against hail by means of electric niagaras in France, Lasnier.....	511
"Gnamma holes" and "night wells," Maclaren.....	511
The action of an alkaline natural water on lead, Liverseege and Knapp.....	511
Water purification and sewage disposal, Tillmans, trans. by Tayler.....	511
Scientific sewage and garbage disposal.....	512
Sewage sludge disposal.....	512
The Cairo sewage farm at Gebel el Asfar, Smith.....	512

SOILS—FERTILIZERS.

Agricultural chemistry—chemistry of the soil, André.....	512
Methods and aims of soil investigation and teaching, Blanck.....	512
Soil analysis, Gomez.....	513
Chemical composition of soils, Vernadskii.....	513
Colloidal chemistry and its importance in soils, Niklas.....	513
The climatic soil zones and their characteristic soil formations, Ohly.....	514
Review of climatic soil zones, Vogel von Falckenstein.....	514
Land climate and sea climate high moors, Stremme.....	514
Properties of the peat soils of Picardy, Coquidé.....	514
Appearance of bleached soil and ortstein in the North Sea marshes, Schucht..	514
Productiveness of soils poor in mineral plant food, Vogel von Falckenstein....	514
Polygon soils and "thufur" on Iceland, Thoroddsen.....	515
Problems in the study of forest soils, Borghesani.....	515
The gases of swamp rice soils, Harrison and Subramania Aiyer.....	515
The organic constituents of soils.....	516
Soil studies by the aid of their water solutions, Ballenegger.....	516
Ultramicroscopy of soil extracts, Muravjanskii.....	516
Microflora of the Roman experimental field, Perotti.....	516
A study of the formation of nitrates in various types of Virginia soil, Fred....	516
Nitrification in acid or nonbasic soils, Temple.....	517
The fertility of the soil, Russell.....	517
The increase of plant food in soils, Gimingham.....	517
Tank experiments on certain salts in sandy loam and adobe soils, Hare et al..	517
Oat sick land, Fowlie.....	518
[Unproductive peat or muck soils], Wiancko.....	518
Reclamation of an unproductive soil of the Kankakee marsh region, Abbott et al.	518

The law of minimum, von Rümker.....	519
The influence of fertilizing on the resistance of grain to hail, Gaul.....	519
A brief account of trials with lime fertilization, Bolin.....	519
Lime-magnesia fertilizers, Marre.....	519
Lime-magnesia ratio in the cultivation of grain, Pisciotto.....	519
Sponges as a fertilizer, Smith.....	519
Composts, Anstead.....	520
Fertilizers in Japan, Gassett.....	520
Report of analyses of commercial fertilizers collected during 1913.....	520

AGRICULTURAL BOTANY.

Introduction to botany, Bergen and Caldwell.....	520
Popular botany: The living plant from seed to fruit, Knight and Step.....	520
Plant life and plant uses, Coulter.....	520
The useful plants of the Dutch East Indies, Heyne.....	521
Northwest flora, Frye and Rigg.....	521
Attempts to grow mistletoe on monocotyledons, Heinricher.....	521
Ripening and rest period of mistletoe seeds and their germination, Heinricher.....	521
The rôle of acids in germination, Promsy.....	521
The influence of light on seed germination, Baar.....	522
Relationship between the weight of the bean seed and its germination, Harris.....	522
Alcohol formation by sprouting wheat, Kostytschew and Scheloumoff.....	522
The respiration of living and of killed wheat seedlings, Kostytschew et al.....	522
Influence of location on leaf development of <i>Ipomœa pes-capræ</i> , Kamerling.....	522
Is there mutual stimulation of plants through root influence? Lyon and Bizzell.....	522
Secretion by roots of substances toxic to the plants, Molliard.....	523
The root nodules of the Podocarpeæ, Bottomley.....	523

EXPERIMENT STATION RECORD.

VOL. XXX.

ABSTRACT NUMBER.

No. 6.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

An investigation of phytin, R. H. A. PLIMMER and H. J. PAGE (*Biochem. Jour.*, 7 (1913), No. 2, pp. 157-174).—Data are given regarding the determination and amounts of phosphorus, calcium, magnesium, carbon, and hydrogen in commercial phytin and phytin obtained from wheat bran.

It is shown that the inorganic phosphates in phytin can be easily determined by precipitation with a solution of ammonium molybdate in seminormal nitric acid at room temperature. The amount of calcium present can be estimated by precipitation as calcium oxalate, but it is much more easily ascertained by precipitation as calcium sulphate. Magnesium can be determined as magnesium pyrophosphate. Much difficulty was experienced in the removal of the calcium from phytin in the preparation of phytic acid. This fact has already been noted by other authors. Inositol was not obtained quantitatively as a result of hydrolyzing phytic acid with an acid. The authors, like Levene, are inclined to believe that another organic constituent is present in phytin. The work on the production of inositol by the hydrolysis of phytic acid is to be continued. A concise review of work previously published on this topic is included.

The constitution of the luteins, C. SERONO (*Arch. Farmacol. Sper. e Sci. Aff.*, 14 (1912), No. 11, pp. 509-511).—A criticism of the methods employed and the results obtained by other workers in a study of the lutein of hen's egg yolk (*E. S. R.*, 27, p. 611). It defends previous results obtained by the author (*E. S. R.*, 26, p. 503), which disagree with those criticized.

Comparison of methods for the preparation and determination of cholesterol, J. S. HEPBURN (*Abs. in Biochem. Bul.*, 2 (1913), No. 7, pp. 467, 468).—These studies, which were made with material obtained from brain tissue and gall stones, resulted in showing that the iodine reagent used in fat analysis can not be used for the volumetric determination of cholesterol. The methods compared were those of Hübl, Hanus, and Wijs. The lowest results were given by the Hübl method. "There was a marked tendency, especially with the Hanus and Wijs methods, for the iodine number to become higher the greater the excess of the iodine reagent. However, the iodine numbers were not simple multiples of 65.7, hence the presence of a second double bond in cholesterol is doubtful."

In the quantitative determination of cholesterol as free alcohol it was found that the modifications of Ritter's method were unsatisfactory. "When carbon dioxide was used to neutralize the excess of sodium ethylate, divergent results

were obtained: 99.9 per cent and 92.43 per cent of the cholesterol taken was recovered. When hydrochloric acid was used to neutralize the excess of sodium ethylate, the results were still less satisfactory, 64.34 to 89.1 per cent of the cholesterol taken being recovered. The gravimetric determination as cholesteryl benzoate is not quantitative; only 24.29 to 61.79 (average 42.86 per cent) of the cholesterol taken was recovered. The gravimetric determination of cholesterol as the free alcohol by Cappenberg's method gave excellent duplicates; 94.47 and 94.37 per cent of the cholesterol taken was recovered. The gravimetric determination of cholesterol as digitonin cholesterid was the most accurate and most satisfactory of the methods studied. From 93.63 to 103.02, average 97.37 per cent, of the cholesterol taken was recovered."

Biochemical synthesis of glucosids from polyhydric alcohols: Glucosids from glycerol and glycol, E. BOURQUELOT and M. BRIDEL (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 8, pp. 405-408).—A report of a study of the production of glucosids from glycol and glycerol. The reaction proceeds more quickly with the former. The synthesizing enzyme came from bottom fermentation yeast.

On the nature of the sugars found in the tubers of arrowhead, K. MIYAKE (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 221-229).—This paper embodies the results of a study on the nature of the sugars found in arrowhead tubers (*Sagittaria sagittifolia forma sinensis*), and forms a part of an investigation on the sugars contained in the underground reserve organs of plants. The reducing sugars present in arrowhead tubers were found to consist of both glucose and fructose. It was not definitely decided whether or not galactose was present. A nonreducing sugar believed to be raffinose was found, but maltose, pentose, and mannose, free or combined, were not noted.

The starch content of cassava roots, A. W. K. DE JONG (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Agr. Chem. Lab.*, No. 5 (1913), pp. 18).—A study of the composition of cassava roots. Although a high specific gravity of the root may indicate a high starch content, it has been found that this is not always true. More accurate figures were obtained from the determination of the total solids.

Notes on the chemical nature of the "tannin masses" in the fruit of the persimmon, E. D. CLARK (*Biochem. Bul.* 2 (1913), No. 7, pp. 412-418).—"Tannin masses from the fruit of the persimmon, by hydrolysis with weak acid or alkali, yield tannin, phloroglucinol, and considerable insoluble colloidal residue. Hydrolysis of such tannin masses does not produce hexose or pentose.

"The nature of the union between the tannin and phloroglucinol is unknown, but it is probably similar to that of the phloroglucin-tannoids in various plants.

"The colloidal residue that resists hydrolysis seems to be a cellulose-like substance which readily forms gelatinous masses with water or alkaline solutions. Quantitative studies on large amounts of this third substance are desirable.

"In the presence of phloroglucinol, the ferric chlorid test for tannin is unreliable.

"A study of the conditions necessary for the formation, and also the hydrolysis, of the phloroglucinol-tannin combination might help to explain the nature of the ripening process in persimmons."

See also previous notes by Lloyd (*E. S. R.*, 25, p. 28; 26, p. 564.)

The occurrence of barium in tobacco and other plants, J. S. McHARGUE (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 6, pp. 826-834).—The presence of barium was noted in the leaves, base, stalks, and roots of tobacco plants gathered in 1910, 1911, and 1912. The amount found in the dry leaves was on the average in 7 samples 0.0399 per cent as barium sulphate (maximum 0.074, minimum 0.0096 per cent); in the stalk the average for 8 samples was 0.0396 per cent

(maximum 0.068, minimum 0.016 per cent); base (1 sample) 0.15 per cent; and root (1 sample) 0.115 per cent.

The barium sulphate content of other plants and materials which were examined was as follows: Corn stover, in dry plant, 0.014 per cent; corn stalks (stubs ad base) in ash, 0.055; corn roots and rootlets, in ash, 0.022; soy beans, best white (whole plant), in dry plant, 0.005; soy beans, China (beans), in dry plant, 0.0014; alfalfa (as cut), in dry plant 0.0132; hemp, in dry plant, 0.0036; burdock root, in ash, 0.44; blue grass, in dry plant, 0.0078; clover, in dry plant, 0.008; Irish potatoes, in ash 0.016; hazelnut shells, in dry plant, 0.007; sycamore stump (last growth, next to bark), in ash, 0.039; banana stalk (after fruit had been removed), in dry plant, 0.049; coal, in air dry sample, 0.014; soil, dry, 0.08; and soil (coal measures), in dry soil, 0.042 per cent. No barium was found in corn (plant, ear, and cob), soy beans (whole plant), poke root, wheat (grain), hickorynut shells, sycamore stump (heart), or limestone rock.

In contrast to Crawford's findings with plants (E. S. R., 20, p. 280), 2 tobacco plants yielded barium when extracted with water. This barium is probably in combination with organic acids, consequently "in tobacco, a plant whose barium content has not been previously reported upon, the barium varies from the normal content of other plants, both wild and cultivated, to approximately twice the maximum reported in locoweed. . . . The occurrence of barium in the live cells of the higher plants suggests that possibly this metal may function in metabolism."

See also previous note (E. S. R., 27, p. 580).

About a hemagglutinin in the Euphorbia, M. VON EISLER and L. VON PORTHEIM (*Centbl. Bakt. [etc.]*, 1. Abt., *Orig.*, 66 (1912), No. 2-4, pp. 309-316; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., *Ref.*, 55 (1912), No. 19, p. 581).—In the milky juice of the Euphorbia hemagglutinins were often noted. These substances were present not only in the seed but also in the vegetative parts of the plant.

Enzymatic cleavage of hippuric acid by mold fungi, A. W. DOX and R. E. NEIDIG (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 85 (1913), No. 1-2, pp. 68-71; *abs. in Science, n. ser.*, 37 (1913), No. 957, p. 683).—"The formol titration method of Sörenson was found admirably adapted to a study of enzymatic cleavage of hippuric acid. All of the mold species examined [*Aspergillus niger*, *A. fumigatus*, *A. clavatus*, *Penicillium camemberti*, *P. roqueforti*, and *P. expansum*] contained an enzym capable of hydrolyzing 80 per cent or more of the hippuric acid in the presence of toluol. The age of the culture (1 to 4 weeks) seemed to have little influence upon the amount of enzym. The enzym was produced in all cases in the absence of the corresponding zymolyte from the medium."

Taka-diastase was also studied in this connection.

Cleavage of pyromucuric acid by mold enzymes, A. W. DOX and R. E. NEIDIG (*Biochem. Bul.* 2 (1913), No. 7, pp. 407-409).—As none of the heterocyclic analogues of hippuric acid have been studied with reference to their cleavage an investigation was made with pyromucuric acid and taka-diastase, emulsin, and press juices from the following species of mold: *Aspergillus fumigatus*, *A. niger*, *A. clavatus*, *Penicillium roqueforti*, *P. camemberti*, *P. expansum*, and *Fusarium oxysporum*. As a measure of the cleavage the formol-titrimetric method was used. The amount of cleavage was less than that which was previously noted with hippuric acid. Figures relative to the formation of ammonia are also included, but ammonia is not regarded as a direct cleavage product of pyromucuric acid.

The enzymes of washed zymin and dried yeast (Lebedew): I, Carboxylase, A. HARDEN (*Biochem. Jour.*, 7 (1913), No. 2, pp. 214-217).—"Zymin and dried yeast (Lebedew) after being freed from coenzym by washing, and thus rendered incapable of fermenting glucose, readily decompose pyruvic acid into carbon dioxid and acetaldehyde, provided that the acidity of the solution is kept low."

Did von Wittich antedate Ostwald in the definition of enzym action? W. N. BERG (*Biochem. Bul.*, 2 (1913), No. 7, pp. 441-445).—A historical discussion in regard to priority.

The precipitation of enzymes from their solutions by moist aluminum hydroxid, W. H. WELKER and J. MARSHALL (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 6, p. 822).—The enzymes studied were peroxidase (water extract of potato), oxidase (water extract of potato), amylase (saliva), pepsin (water solution of commercial pepsin), pepsin (0.2 per cent hydrochloric acid solution of commercial pepsin), rennin (water solution of commercial rennin), trypsin (water solution of commercial trypsin), trypsin (0.5 per cent Na_2CO_3 solution of commercial trypsin), trypsin (30 per cent alcohol extract of pancreas), trypsin (30 per cent alcohol extract of pancreas plus an equal volume of 1 per cent Na_2CO_3 solution), amylase (30 per cent alcohol extract of pancreas) and lipase (30 per cent alcohol extract of pancreas).

All the enzymes, with the exception of amylase, were completely removed from the solution by aluminum hydroxid. "The only zymogen studied was pepsinogen (prepared by extracting the mucous membrane of the stomach of pigs with 50 per cent glycerol solution), which in 10 per cent and in 25 per cent glycerol solution is removed quantitatively only with the greatest difficulty."

The precipitation of colloids by means of aluminum hydroxid, J. MARSHALL and W. H. WELKER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 6, pp. 820-822).—"The following solutions were subjected to the treatment with aluminum hydroxid. In each case the colloidal material was removed absolutely quantitatively: Copper, gold, platinum, sulphur, nickel sulphid, cobalt sulphid, cupric hydroxid in NaOH, Prussian blue, Congo red (indicator solution), azolitmin, litmus (neutral), litmus (red), litmus (alkaline), starch paste, soluble starch, erythroextrin, starch iodid, water emulsion of fat (mechanical entangling of fat globules), soap, emulsion of fat in soap solution (including fat and soap), egg albumin, globulin (edestin in 5 per cent NaCl), gelatin, casein (in one-half saturated lime water) glutenin (in 0.5 per cent Na_2CO_3), nucleoprotein (in 0.5 per cent Na_2CO_3), gliadin (in 70 per cent alcohol), ovomucoid, acid metaprotein (in 0.1 per cent HCl), primary proteose, secondary proteose, milk (including fat and protein), and blood serum (protein).

"The use of aluminum hydroxid, therefore, would appear to be well adapted for preparing oxyhemoglobin from erythrocytes because it removes protein from the blood serum mingled with the dissolved sedimented erythrocytes and also the precipitable protein of these cells themselves, yielding a filtrate from which, as we have found by experiment, oxyhemoglobin more readily crystallizes and in a much purer state than by any other known method."

The direct determination of elementary nitrogen with the aid of calcium carbid, B. NATUS (*Ztschr. Analyt. Chem.*, 52 (1913), No. 5, pp. 265-292, fig. 1; *abs. in Chem. Ztg.*, 37 (1913), No. 68, *Repert.*, p. 310).—For the absorption of the nitrogen a mixture consisting of 10 parts of technical carbid and 1 part of calcium chlorid, which was powdered and previously heated to redness, is used. The absorption takes place in a porcelain tube heated to redness, and for displacing, hydrogen of known nitrogen content is passed through the tube. The nitrogen is then determined in the carbid mixture by Wilfarth's modification

of Kjeldahl's method, which consists of decomposing the mixture with fuming and concentrated sulphuric acid and 1 drop of mercury. The error with dry gases was on an average 0.75 per cent.

The advantages of the Wilfarth method over the Kjeldahl and phenol-sulphuric acid methods are shown.

A micro-Kjeldahl apparatus, M. MORSE (*Abs. in Biochem. Bul.*, 2 (1913), No. 7, pp. 457, 458, pl. 1).—This is a combination of the apparatus designed by Fritz Pregl for determining nitrogen in small quantities of material and the fume absorber devised by Folin and Denis noted below. The apparatus is regarded as equally serviceable with that devised by Sy (*E. S. R.*, 28, p. 311).

An apparatus for the absorption of fumes, O. FOLIN and W. DENIS (*Jour. Biol. Chem.*, 11 (1912), No. 5, pp. 503-505, figs. 2).—An inexpensive apparatus for this purpose is described and illustrated.

A modification of a method for examining fermentation gases, W. FRIEBER (*Centbl. Bakt. [etc.]*, 2. Abt., 36 (1913), No. 19-25, pp. 438-443, fig. 1).—What is claimed to be an improvement on Burri and Duggeli's apparatus and method^a is described.

The volumetric determination of manganese in rock, slags, ores, and spiegels, F. J. METZGER and L. E. MARRS (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 2, pp. 125, 126).—This is an application of a method previously noted (*E. S. R.*, 24, p. 211) to the substances stated above.

Importance of the error of analysis in questions relating to the nitrogen economy of arable soils, T. PFEIFFER and E. BLANCK (*Landw. Vers. Stat.*, 78 (1912), No. 5-6, pp. 367-374; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 604, I, p. 238).—"A final attempt was made to obtain a satisfactory nitrogen balance with the experimental soils at Breslau. Six plats (9 square meters each) were selected, which had given similar amounts of crops during 2 years, and from each plat 5 samples of soil were taken. Ten or 12 nitrogen estimations were made with each sample. The experimental error was found to be ± 0.00086 , which would correspond with 25.8 kg. of nitrogen per hectare to a depth of 25 cm. if the weight of the soil is taken as 3,000,000 kg., or 32.2 kg. if the total weight of the soil is taken as 3,750,000 kg. As this number has to be multiplied by 3, it would only be possible to show a difference exceeding 77.4, or 96.6 kg. of nitrogen per hectare. With fewer samples or analyses the error would, of course, be greater. It must also be borne in mind that the nitrogen of crops is not all derived from the surface soil, but from the subsoil as well."

Note on the volatility of sulphuric acid when used in vacuum drying, H. C. GORE (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 259-261, fig. 1).—In the course of some experiments in drying in high vacuum it was noted that sulphuric acid, when used as a desiccant, volatilizes, and when organic substances such as flour are dried, they become darkened in color. In order to determine the extent to which the acid volatilizes, a Hempel desiccator was charged with 7 Petri dishes, placed one above the other, and containing potassium hydroxid, which was then exposed to the action of sulphuric acid for a period of 237 days at room temperature and at a vacuum somewhat less than 1 mm. The amount of sulphuric acid collected in dish No. 1 was 0.2133, in No. 2, 0.044, in No. 3, 0.0169, in No. 4, 0.0061, in No. 5, 0.0072, in No. 6, 0.0026, and in No. 7, 0.0029 gm., or a total of 0.293 gm.

It is stated that lime may be successfully substituted for sulphuric acid.

Direct determination of moisture in foods and miscellaneous materials by distillation, F. MICHEL (*Chem. Ztg.*, 37 (1913), No. 35, pp. 353-355, figs. 4).—

^a *Centbl. Bakt. [etc.]*, 1. Abt., Orig., 49 (1909), No. 2, pp. 145-174.

The method consists of placing the substances under examination in a 300 cc. Erleumeyer flask containing 150 cc. of a mixture consisting of one-third toluol and two-thirds xylol. Paraffin having a boiling point higher than 100° C. can also be employed, but it has no advantages over the substances mentioned. The mixture is distilled into a 10 cc. graduated collection tube provided with a funnel having a glass stopcock ground in. The amount of water present in the tube is read off, and after applying certain corrections the percentage is computed. Several optional forms of the collecting device are also described.

The results of tests of the method with honey, butter, and milk showed that it gives good results.

A special flask for the rapid determination of water in flour and meal, J. H. Cox (U. S. Dept. Agr. Bul. 56 (1914), pp. 7, figs. 7).—A description is given of a special flask, to be used in connection with the Brown-Duvel moisture-determining apparatus (E. S. R., 24, p. 215), and designed for commercial work.

The flask may be constructed of either copper or glass. It is double walled and has an inner capacity of about 900 cc. A single-walled flask is not suited for testing finely ground substances and the meal under test very frequently burns badly at the bottom. The method is deemed rapid and accurate.

A detailed description of the entire Brown-Duvel apparatus and method is given, with a special form of graduate for collecting the water distilled from the grain.

Determination of moisture in maize for export, H. J. VEPOND (Union So. Africa Dept. Agr. Rpt. 1910-11, pp. 395-397).—A series of tests were carried out to determine the reliability of results obtained by the Brown-Duvel method (E. S. R., 18, p. 1122).

In all cases the temperature was allowed to reach 190° C. before the burner was removed. The time required to reach 190° varied from 14 to 20 minutes; the highest temperature obtained after removing the flame was 196°.

The results obtained were compared with check determinations made with ground material and drying in a steam oven. In the case of the ordinary steam oven method there was a slight gain in weight after the material had been dried for 3½ hours, presumably due to an oxidation of the oil present in the cereal.

The results with the Brown-Duvel apparatus were about 2 per cent too high. "The net conclusion is that the Brown-Duvel tester gives very reliable results when worked under uniform conditions, but the figures are rather high under those prescribed by the originators of the method. This can easily be remedied either by deducting say 1 per cent from the readings thus obtained, or by adopting a slightly lower temperature for working. The grain after testing invariably shows a certain amount of blackening, principally in the embryo, indicating the destruction of organic matter.

"Similar tests with soy beans (taking the temperature up to 190° in 20 minutes in such a way that the final temperature reached after removing the flame does not exceed 192°) gave readings about 3 per cent higher than those obtained by the ordinary (steam oven) method."

A few tests were made also to determine the total loss of weight in grinding. The amount of grain weighed off was 48.649 gm. and the amount obtained after grinding was 48.524 gm. "This loss probably includes some of the meal, so that it represents the maximum loss which can be attributed to evaporation of water from the grain during grinding."

Contribution to the study of flour, E. GURY (Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndtsamt., 4 (1913), No. 3, pp. 113-121, fig. 1).—This is a study of the methods for determining the moisture content of flour, and was made

because many divergent figures for the normal moisture content are given in the literature.

The wheat flours studied came from various sources. The figures obtained in these experiments varied between 12.75 and 15.09 per cent, with one exception, a flour prepared in the laboratory, which showed only 10.83 per cent. The moisture content of barley, rye, oat, rice, and bean flour varied between 10 and 12.8 per cent. In this work a modified Hoffmann method and ordinary petroleum were employed. Toluene when used in the method forms an emulsion.

In order to determine the fixation of water by flour a method was devised which consisted of shaking with water a known weight of flour in a tube graduated in $\frac{1}{10}$ cc., then centrifuging and reading the volume of the sediment. A similar test was made with the same quantity of flour in another tube, but using 95 per cent alcohol instead of water, the difference between the 2 figures constituting what the author terms the water-alcohol difference. This test serves to differentiate many kinds of flour, as the water-alcohol figures for wheat and bean flour are negative and all others (rye, rice, potato, oat, etc.) positive. The higher the negative figure for wheat flour, the better the product.

Nitrogen was determined by the Kjeldahl method as described in the Swiss Food Manual; gluten by König's method. The gluten percentage varied between 6 and 11 per cent when calculated to dry substance. Cellulose was determined by a method which has been employed by the author for cacao products (E. S. R., 28, p. 711). Gliadin was determined according to Abderhalden's method (E. S. R., 23, p. 410) but the results obtained were not accurate.

The determination of water in plant substances with F. Hoffman's moisture-determining apparatus, ST. VON HAYDIN (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 25 (1913), No. 3, pp. 158-160, fig. 1).—The apparatus, which has proved practical for soils, brewers' grains, malt, hops, barley, flour, potato chips and flakes, starch, and yeast, consists of a copper distilling flask with a thermometer and funnel. Into it is placed 20 gm. of the finely ground substance, 200 cc. of liquid paraffin, and 10 cc. of turpentine. The temperature is raised in 8 minutes to 180° C., and then 10 cc. more of turpentine is added and the temperature raised to 200° for 5 minutes. The water and turpentine pass through a condenser into a graduated cylinder. The number of cubic centimeters in the water layer multiplied by 5 gives the percentage of moisture.

The sample is placed in a copper wire cylinder or holder 5 cm. in diameter, which is lowered into the paraffin. It keeps the substance from sticking to the distilling vessel and does away with filtering after each determination. The determination can be made in 20 minutes when using the holder.

This method with cabbage checked to within an average of 0.3 per cent with the water oven method, which takes 4 hours to obtain constant weight.

Investigations in regard to varieties of egg yolk, with a contribution in reference to the relation of the various kinds of yolk to one another, E. EMMERICH (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 17 (1913), No. 3, pp. 299-304).—It has been previously shown by Uhlenhuth and Ottolenghi that egg yolk could be detected with the precipitation method in margarin, noodles, etc. Schütze (E. S. R., 16, p. 845) also worked on this problem. After describing the technique used in preparing the precipitating serum, the author reports tests made with noodles (prepared in the laboratory and purchased in the open market), macaroni, etc. The results show that a highly specific antiserum can be prepared which will detect egg yolk in baked goods, but that with noodles, macaroni, and similar goods the results are often difficult to ob-

tain. Numerous fish eggs as caviar, carp, and red bream eggs and the yolk from the turtle give positive reactions with fowl egg yolk serum. The ovary of the turtle gave negative results.

A new instrument for measuring strength of alcoholic liquids (*Sci. Amer. Sup.*, 75 (1913), No. 1952, p. 342).—A description of Contassot's ebullioscope, which is intended for the rapid determination of alcohol in wine, beer, cider, etc. The operation requires from 5 to 6 minutes, and determines the boiling points of both the liquid and of pure water. "The usual method adopted for this purpose is to determine the boiling point of the liquid; this alone, however, is not enough, the boiling point of pure water must always be determined at the same time, since it depends on the barometric pressure."

An attempt to estimate the vitamin fraction in milk, C. FUNK (*Biochem. Jour.*, 7 (1913), No. 2, pp. 211-213).—The solids obtained from the evaporation of milk from London dairies in vacuo at 30° C. were dried at constant weight and shaken with alcohol for two hours. A portion of this alcoholic extract was evaporated to dryness and the residue extracted with water, and from the aqueous solution thus obtained the vitamin was precipitated with a 10 per cent solution of phosphotungstic acid.

The amount of beri-beri vitamin, as shown by this method, varied from 10 to 30 mg. per liter of fresh milk. "The figures show the milk after removal of fat by centrifuging has lost about 50 per cent of vitamin and allantoin."

"After the elimination of the vitamin fraction the residual nitrogen amounts to 20 to 50 mg. per liter of milk. This residual nitrogen represents in all probability allantoin. Assuming this to be correct, 1 liter of milk contains 0.06 to 0.15 gm. allantoin, a figure in good agreement with that obtained by Ackroyd by means of a direct method, namely 0.199 gm." It is also interesting to note that in allantoin we have a substance which, like vitamin, is destroyed by boiling.

The problems which have presented themselves in connection with this investigation, it is announced, will be more fully discussed in a later publication.

Aluminum hydroxid as a protein precipitating reagent in the determination of lactose in milk, W. H. WELKER and H. L. MARSH (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 6, pp. 823, 824).—The results obtained with milks (human and cow's), clarified with aluminum cream and the copper sulphate-alkali method, show close agreement when examined for their lactose content. The lactose was determined by the copper reduction method with Fehling's solution, and the reduced copper was estimated by the cuprous iodid method as modified by Low.

Adulteration of milk.—Watering, C. PORCHER (*Indus. Lait*, [Paris], 38 (1913), Nos. 31, pp. 503-505; 32, pp. 511-518, fig. 1; 33, pp. 532-536; 34, pp. 547-550; 35, pp. 565-567; 36, pp. 577, 578).—This is a discussion and study in regard to the value of different methods for detecting adulterations in milk, including the cryoscopic or freezing test and the refractive index and specific gravity tests. The physiology of milk secretion is also considered, and it is shown wherein the natural watering of milk by an increased allowance of drinking water is unimportant.

A rapid method for determining the addition of water to buttermilk, H. M. HÖYBERG (*Ztschr. Fleisch u. Milchhyg.*, 23 (1912), No. 5, pp. 104-107).—In Denmark the addition of ice directly to buttermilk for cooling purposes is prohibited, consequently in controlling the milk supply the presence of an excess of water from this source must be considered. As nitrates are not always present in Danish waters, the test for nitrates can not be used. The determination of fat and fat-free dry substances can not be employed because the results vary too much. A better procedure seems to be to determine the specific gravity

of the whey of the buttermilk, and as a result of 112 determinations it was found that unadulterated buttermilk possesses a gravity varying from 1.025 to 1.0275. Accordingly, buttermilk having a gravity below 1.025 can be considered adulterated.

A rapid method of determining the solids in evaporated milk, O. F. HUNZIKER (*Indiana Sta. Rpt. 1913, p. 43*).—The formula given below was devised for the purpose of rapidly determining the total solids present in evaporated milk:

$$\left[\left(\frac{145.5}{145.5 - B} \right) \times 1,000 - 1,000 \right] \times \frac{1}{4} + 1.2 \times f$$

B represents the Baumé hydrometer reading at 60° F. and *f* the percentage of fat in the milk. The Baumé reading is not always conveniently determined at 60°, but tests showed that it may be correctly calculated from the observed reading at any temperature by adding to the observed reading 0.0313 points for every degree Fahrenheit over 60°.

Studies on flax retting, T. TADOKORO (*Jour. Col. Agr. Tohoku Imp. Univ., 5 (1913), No. 2, pp. 31-55*).—This investigation reports the results of a study of the changes in different stages of flax retting and the chemical nature of the constituents of the flax stem. The results of studies of the micro-organisms concerned with the retting process are reserved for future publication.

The flax used was typical in size, quality, and ripening, and was produced in the vicinity of Sapporo. The retting was done in a large crate according to the usual method in Hokkaido.

The author summarizes the results of his investigation as follows: "Cutin is the essential constituent of the cuticle, and tannin is found in the epidermal cell. The fiber consists of cellulose with a small quantity of pectin compounds, protein and fat-like substance as its integral part. On the other hand, the cell wall of the cambium, epidermis, and parenchyma are made up principally of pectin compounds with a small quantity of cellulose. The middle lamella of fibers is composed mainly of pectin compounds. Lignin forms the chief constituent of the cell wall of the xylem, while a pectin compound forms that of the pith.

"Water retting involves anatomical as well as chemical changes of the flax stem. On the first stage of retting, we observe the destruction of the cambium layer, and then of parenchyma, accompanied with the separation of fiber bundles. As the retting proceeds, the isolation of the fiber itself and the detachment of the cuticle take place. Nearly all of the constituents of the stems are subjected to chemical changes which are induced by the combined action of micro-organisms and of the extractive power of water. The loss of weight in the stem may therefore be taken as a measurement of the retting grade.

"The anatomical and chemical changes take place not on all parts of stem but only on the bark portion, i. e., the outer layers of cambium. The xylem and pith remain almost unchanged.

"The essential matters which are lost during retting are pentosan, or gummy substance, in the bark portion and fiber (cutin, lignin, and cellulose). Of the three ingredients composing pentosan-free fiber, the lignin remains almost unchanged, cellulose loses a small quantity, this being accompanied by the destruction of surrounding tissues of fiber bundles in the bark portion, and cutin is detached mechanically in the later stage of retting, with the destruction of other tissues.

"Among other ingredients, tannin is lost completely. The larger part of the mineral matters and of glucose are also lost. The quantity of protein and fat is very small and their loss may be neglected in consideration.

"The gummy substance, or pentosan, in the bark portion of the stem is made up largely of xylan and araban, with a small quantity of methyl pentosan."

Progress made in the manufacture of beet sugar in 1912, E. O. VON LIPPMANN (*Chem. Ztg.*, 37 (1913), No. 19, pp. 193-195).—This deals with the progress made in the agricultural, technical, chemical, and other phases of this industry.

METEOROLOGY—WATER.

Reports on agricultural meteorology (*Inst. Internat. Agr. [Rome], Actes 4. Assemblée Gén., 1913, pp. 395-459*).—Reports presented at the Fourth General Assembly of the International Institute of Agriculture of Rome in May, 1913, by L. Dop of France, W. N. Shaw of England, Kuster of Germany, P. Rey of France, and P. Broounoff of Russia are given. These reports deal more particularly with the organization of agricultural weather services in the countries named.

Agricultural meteorology, M. YRANZO (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 2, pp. 8*).—This article advocates particularly more complete systems of meteorological observations and a thorough distribution of forecasts. It proposes especially the establishment of a system of "régime types" of weather, the effects of which in a given region have been carefully worked out. It is thought that by the use of this system the transmission of weather forecasts can be greatly simplified and extended.

The method of forecasting proposed by Guilbert is approved, but its full application is not considered possible without a great extension of international observations reported to a central bureau.

A short list of more recent publications bearing on this subject is given.

Means of making weather forecasts more useful in the open country, E. VANDERLINDEN (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 1, pp. 7*).—A general plea is made for the wider dissemination of popular information relating to meteorology so that farmers may have at least a sufficient scientific knowledge of the subject to interpret the weather maps. An increase in secondary stations so that the necessary information may be given out promptly locally is recommended, particularly for Belgium.

Report of the Iowa Weather and Crop Service for 1912, G. M. CHAPPEL (*Iowa Yearbook Agr.*, 13 (1912), pp. 1-48, fig. 1).—This report summarizes data contained in the monthly and weekly bulletins issued by the Iowa Weather and Crop Service in cooperation with the Weather Bureau of this Department. The data were obtained from the 118 cooperative meteorological stations in the State and from the U. S. Weather Bureau stations at Des Moines, Davenport, Dubuque, Charles City, Keokuk, and Sioux City, Iowa, and Omaha, Nebr.

Division of meteorology, N. HELME (*Rhode Island Sta. Rpt. 1912, pp. 215-230*).—Daily observations at Kingston on temperature, precipitation, wind, and cloudiness for each month of the year ended June 30, 1912, are summarized in tables and notes. The mean annual temperature was 46.8° F.; the maximum 98°, July 10, 1911; the minimum -10°, February 11, 1912. The annual precipitation was 59.87 in., the number of clear days 150, and the prevailing direction of the wind west.

English climate and some of its variations, W. MARRIOTT (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 2, pp. 5*).—Observations on temperature, rainfall, rain days, clouds and humidity, sunshine, and winds at all of the meteorological stations in England and Wales during the 30 years 1881-1910 are briefly summarized in this article to indicate the characteristic features of English climate and some of the more important variations to which it is subject.

Climate and meteorology of Australia (*Off. Yearbook Aust.*, 6 (1901-1912), pp. 67-102, figs. 8).—This is a summary in the usual form for the Australian Commonwealth up to the end of 1912.

The station of agricultural meteorology at Riudabella, J. P. GIL (*X. Cong. Internat. Agr. Gand*, 1913, Sect. 2, Question 2, pp. 9).—The character and purpose of the observations made at this station are briefly discussed, and observations on temperature, rainfall, sunshine, cloudiness, and wind movement during the years 1908-1912 are summarized.

The rains of the Nile Basin and the Nile flood of 1911, J. I. CRAIG (*Survey Dept. Egypt Paper* 27 (1913), pp. 110, pls. 9, figs. 2).—Observations similar to those of previous years (*E. S. R.*, 28, p. 315), are included in this report.

As regards the accuracy of discharge measurements and existing inconsistencies among the discharge results, the author is of the opinion that "some of these inconsistencies can doubtlessly be traced to . . . scour and silting of the channel, but these disturbances are not systematic, and in the long run or over a series of gages average out. . . . However, certain systematic causes are at work, and insufficient attention has hitherto been paid to turbulence, whose effect is always to give a discharge apparently too great. On this hypothesis, many inconsistencies, at present difficult of explanation, can be qualitatively explained, and when an adequate means of measuring turbulence is found, the quantitative explanation will follow."

Protection against hail by means of electric niagaras in Beaujolais, France, E. LASNIER (*Vie Agr. et Rurale*, 2 (1913), No. 49, pp. 585-588, figs. 2; *Deut. Landw. Presse*, 41 (1914), No. 3, p. 28).—The general conclusion drawn from a review of the experiments in Beaujolais during 1912 and 1913 is that the "electric niagaras" proposed by Beauchamp and Négrier were ineffective as a means of protection against hail.

"Gnamma holes" and "night wells", M. MACLAREN (*Geol. Mag. [London]*, n. ser., V, 9 (1912), No. 7, pp. 301-304, figs. 2; *abs. in Geol. Zentbl.*, 19 (1913), No. 1, p. 21; *Wasser u. Abwasser*, 7 (1913), No. 9, p. 361).—The author describes the appearance and origin of these water supplies. The "gnamma holes" are said to be formed by the erosive action of wind and subsurface water, while the "night wells," in which water appears only at night, are caused by the arching of the gneiss sheets during the heat of the day, causing the water to recede and reappear only at night when the sheets have cooled and flattened.

The action of an alkaline natural water on lead, J. F. LIVERSEGE and A. W. KNAPP (*Chem. News*, 108 (1913), No. 2811, p. 176; *abs. in Chem. Abs.*, 8 (1914), No. 2, p. 337).—Tests of a municipal water supply relative to its action on lead pipe and sheet lead showed an eroding but not a solvent action which is said to be due to the action of oxygen in the presence of water.

"As a rule a pipe becomes with age less sensitive to the action of the water but the rate of this change varies greatly with different pipes. Treatment of new pipes with a dilute solution of potassium permanganate gave them a considerable power of resistance to the action of the water. . . . The amount of lead eroded is affected by the distance from the lead to the water surface, is generally proportional to the area of the surface of the lead exposed, and does not depend on the volume of the water. . . . Four parts per 100,000 of calcium carbonate gave protection, and as little as two parts per 100,000 of calcium bicarbonate were sufficient practically to prevent erosion."

Water purification and sewage disposal, J. TILLMANS, trans. by H. S. TAYLOR (*New York*, 1913, pp. XV+143, figs. 21).—It is the purpose of this book to give a survey "as complete as possible of the present position in regard to water purification and sewage disposal" from the German point of view. "The careful attention which has been paid by the German authorities during the

past few decades to the provision of suitable water supplies and the adequate disposal of sewage, renders the present critical survey of modern methods . . . useful to the English reader."

The first half of the book is devoted chiefly to modern processes of purification of water for drinking purposes on both large and small scales. The purification of water for industrial purposes is also briefly touched. The second half discusses the mechanical and biological purification and disposal of domestic sewage, particularly noting the advantages and disadvantages of sewage farming and the use of screen and grit chamber residues and sludge as fertilizers.

The main purpose of the process of sewage farming is considered to be sewage purification rather than agricultural benefit, and "it is inadvisable on this account for towns to lease their sewage farms to farmers. . . . In all circumstances purification of the sewage before disposal on the farm is to be recommended." The residues from grit chambers and screens are said to contain some plant food elements and may be used as fertilizers though such use is usually offensive. Sludge from sedimentation tanks is said to contain (in dry matter) generally from 2 to 3 per cent nitrogen, about the same amount of phosphoric acid, and about 0.5 per cent potash, but owing to its foul condition and the difficulty and expense of drying, its use as a fertilizer is limited. The purification of industrial sewage is also discussed in some detail.

Scientific sewage and garbage disposal (*Daily Cons. and Trade Rpts.* [U. S.], 17 (1914), No. 29, pp. 449-459).—The methods of sewage and garbage disposal practiced in various places in the United Kingdom, Germany, France, Austria, and Russia are briefly described. It is shown that sewage irrigation and the utilization of sludge and certain garbage products as fertilizer is successfully practiced in many places in these countries, but generally, however, in connection with other methods of disposal.

Sewage sludge disposal (*Chem. Trade Jour.*, 54 (1914), No. 1391, pp. 71-73, figs. 3).—The Grossmann process of treating sludge to free it from fat and fit it for use as a fertilizer, as applied at Oldham, England, is described.

The Cairo sewage farm at Gebel el Asfar, E. C. B. SMITH (*Agr. Jour. Egypt*, 3 (1913), No. 1, pp. 23-27, pls. 4).—This article describes and illustrates by ground sections the geological features and formations of the sewage farm as determined by test borings which indicate its fitness for sewage irrigation.

SOILS—FERTILIZERS.

Agricultural chemistry—chemistry of the soil, G. ANDRÉ (*Chimie Agricole—Chimie du Sol. Paris, 1913, pp. XVI+556, figs. 9*).—This is one of the volumes of Wery's *Encyclopédie Agricole*. It is more than its title indicates, for it discusses the formation, classification, and physical and biological properties of soils as well as the more strictly chemical features of the subject.

The treatment of the subject is encyclopedic, and the book contains a large amount of information drawn from many sources which, however, are often not so clearly indicated by citation of references as the investigator could wish.

The historical development of certain phases of soil investigation is quite fully treated in some cases, but is not always brought up to date. This is notably true in the discussion of the chemistry of the organic matter of the soil in which no account is taken of the recent important work by American investigators.

Methods and aims of soil investigation and teaching, E. BLANCK (*Fühling's Landw. Ztg.*, 62 (1913), No. 13, pp. 462-473; abs. in *Zentbl. Agr. Chem.*,

42 (1913), No. 12, pp. 793, 794).—The author discusses various views on this subject and reaches the conclusion that it should be taught as an individual science from two standpoints, viz, the scientific and the technological.

Soil analysis, G. GOMEZ (*Bol. Dir. Gen. Agr. [Mexico], Rev. Agr.*, 2 (1912), No. 7, pp. 593–607).—The author points out the importance of physical and chemical analysis in soil classification and judgment, and in determining the fertilizer need of soils. He proposes a simple notation which facilitates comparison of the results of physical and chemical analysis.

Chemical composition of soils, V. I. VERNADSKIĖ (*Pochvovĕdĕnie (Pĕdologie)*, 15 (1913), No. 2–3, pp. 1–21).—The author, in the first part of his article, draws attention to the important part played by gases in the physical, chemical, and biological activity of soils, and also to their geological importance. He considers the colloidal soil constituents to be the seat of activity of soil gases, states that these gases or their solutions participate in all the processes of reduction, oxidation, and hydrate formation which occur in the soil, and reviews particularly the activities of nitrogen, hydrogen, oxygen, carbon dioxide, and methane in this respect. The character, properties, and quantitative relations in the soil of gases are said to be strongly influenced by meteorological and biochemical factors.

In conclusion the importance is emphasized of considering not only the solid and liquid soil constituents, but also the soil gases in soil analysis.

In the second part of the article attention is drawn to the elements rubidium, cesium, and thallium, and to their similarity to potassium. Cesium and thallium are disregarded as occurring only in traces, but the rubidium is thought to affect seriously the accuracy of potassium determinations in the ordinary methods of chemical soil analysis, owing to the significant quantities of the former element found in soils and plants and also to the difficulty of distinguishing it from potassium by the ordinary methods.

Colloidal chemistry and its importance in soils, geology, and mineralogy, H. NIKLAS (*Internat. Mitt. Bodenk.*, 3 (1913), No. 5, pp. 383–403, pl. 1).—The author reviews the elements of colloidal chemistry and points out some of its important relations to soils, geology, and mineralogy.

Most soil gels are considered to be reversible, and most soil colloids are considered to be negatively charged, which is said to explain their power for absorbing the positively charged bases of basic salts. Such absorption results in gel formation and better soil structure, as is shown by a series of photographs illustrating typical colloidal reactions, precipitation, and absorption. The absence of electrolytes, or the presence of so-called physiologically basic salts, such as sodium nitrate, is said to cause the formation of soils, which results in a compact, poorly aerated soil structure. In such cases fall plowing is suggested, as it allows the winter frost to form gels in the soil, thus loosening the structure. Heat and dryness are also said to coagulate the soil colloids and improve the structure, but too heavy rains form sols of the reversible gels and also by washing out the soil salts cause a return of the compact, badly aerated structure.

Soil formation by weathering is thought to be based on colloid chemistry, especially the formation of laterite, red soil, ortstein, and clay from feldspar. Colloidal humus is considered to be active in soil formation. The beneficial effect of lime salts on soil structure is attributed to the higher gel forming power of bases of higher valence, and it is stated that the more the effect of the positive ion exceeds that of the negative ion the more beneficial is the effect on the soil structure. The beneficial effect of stall and green manure on the soil structure is attributed to the addition of new colloids, which not only form gels but also dissolve lime.

The climatic soil zones and their characteristic soil formations, C. OHLY (*Internat. Mitt. Bodenk.*, 3 (1913), No. 5, pp. 411-455; *abs. in Rev. Sci. [Paris]*, 52 (1914), I, No. 12, pp. 374-376).—The author distinguishes the climatic zones of the desert, plain, savanna, forest, and tundra on the basis of the forms of vegetation found, and briefly describes their peculiar soil types.

He concludes that the climate is the principal factor in the formation and variation of soil. The more extreme the climate, the more uniform is the soil formation, and the less is the part played by their local condition. On the other hand, a variable climate, with a corresponding distribution of climatic factors, results in soil formations which are due to local conditions as well as climate. On this account the author concludes that the total vegetation forms of a region indicate the nature of the soil and climate, and that a consideration of these should be the basis of soil classification.

Review of climatic soil zones, K. VOGEL VON FALCKENSTEIN (*Ber. Oberhess. Gesell. Nat. u. Heilk. Giessen, Naturw. Abt.*, 5 (1912), pp. 156, 157).—A tabular representation of the processes of soil formation in arid and humid climates is given, which includes particularly podzol, chernozem, and semidesert soils. The difference in soil formation in arid and humid climates is shown to depend on the amount of rainfall, the possibility of evaporation, the difference in seasons, and local influences.

Land-climate and sea-climate high moors, H. STREMMER (*Pochvovedenie (Pédologie)*, 15 (1913), No. 2-3, pp. 59-69).—A distinction is drawn between inland high moors and sea climate high moors, principally by a comparison of their prevailing types of vegetation. The prevailing type of vegetation of the high moors typical of sea climate is said to be the Sphagnum or peat moss, while the majority of the high moors typical of the land climate are said to be wooded with Ericaceae, and have in addition to Sphagnum many forms of vegetation which require a drier soil. Also the Sphagnum formation is covered with bunch grass, and some of these high moors are said to be even too dry for the Sphagnum to thrive.

Properties of the peat soils of Picardy, E. COQUIDÉ (*Ann. Sci. Agron.*, 4. ser., 2 (1913), II, No. 5, pp. 566-582; *abs. in Chem. Abs.*, 8 (1914), No. 6, p. 1179).—This article describes the peat soils of the region and their vegetation, and discusses their analysis as regards plant food and their dryness. The soils are said to consist of a black, very combustible peat, which is very compact, poorly aerated, of improper condition for nitrification, very poor in plant food, and either excessively humid or physiologically dry. The vegetation of the swamp peat soils is hygrophitic, while that of the dry peat lands is typically xerophitic.

The appearance of bleached soil and ortstein in the muck soils of the North Sea marshes, F. SCHUCHT (*Internat. Mitt. Bodenk.*, 3 (1913), No. 5, pp. 404-410).—The author found an apparently widespread formation of bleached soil (Bleicherde) and ortstein in the much weathered muck loam, muck clay, and muck sand soils of the North Sea marshes. The bleached soil contained some plant food, and the ortstein was wet and not hard enough to hinder vegetation.

Some factors of productiveness of soils poor in mineral plant food, K. VOGEL VON FALCKENSTEIN (*Ber. Oberhess. Gesell. Nat. u. Heilk. Giessen., Naturw. Abt.*, 5 (1912), pp. 139-151, fig. 1).—An investigation of forest soils in Germany shows the poor diluvial sands of northern Germany and the sterile colored sandstone soils of middle and southern Germany to contain sufficient mineral food for good forest growth. The diluvial sands are, ordinarily, of good depth, but in these and the sandstone soils a heavy covering of humus causes a formation

of the hard ortstein, which not only decreases the effective depth but also the food supply.

Three types of soil inclined to swamp formation were found in the colored sandstone regions: (1) White soils (Molkenbüden), the weathering product of hard sandstone; (2) red clay, the weathering product of soft stone; and (3) red clay, underlying white soil. The white soils consist of a bleached out surface layer and an impervious substratum. Their characteristic property is a high content of dust and fine matter, and their main difference from the red clay is a lower total clay content but a higher silicate content. Drainage, forestation, mechanical cultivation, and liming are suggested for the improvement of white soils.

Polygon soils and "thufur" on Iceland, T. THORODDSEN (*Mitt. Justus Perthes' Geogr. Anst.*, 59 (1913), Nov., pp. 253-255).—The author reports the apparently widespread formation of the so-called polygon and "thufur" or hilly soils, which, he thinks stand in close genetic relation, in that variable evaporation, freezing, thawing, and the absence of drainage are essential conditions for the formation of both.

The polygon soils are said to occur only in flat soils of mixed clay and tufa, being divided into more or less regular polygons of wet clay, 1 to 1½ meters in diameter, which are separated by frost cracks filled with small stones, tufa, and refuse. Freezing is thought to force the coarse material down and laterally, while thawing, capillarity, and evaporation bring the fine material to the top.

The hilly or thufur soils are described as little knolls from ½ to 2 meters in diameter, and from ¼ to ½ meter high. The upper layer consists of humus and plant residue, and the interior of mixed soil and clay. These knolls are also separated by frost cracks and are thought to be formed in the same manner as the polygon soils, except that the rise of fine matter is more rapid.

Problems in the study of forest soils, G. A. R. BORGESANI (*Gior. Geol. Prat.*, 11 (1913), No. 3-4, pp. 215-222, pl. 1).—The author emphasizes the importance in forest culture of choosing kinds of trees best adapted to the chemical properties of a particular soil, and of fertilization adapted to the kinds of trees chosen. Attention is further drawn to the effect of the litter covering on the conservation of forest soils.

The gases of swamp rice soils, W. H. HARRISON and P. A. SUBRAMANIA AIYER (*Mem. Dept. Agr. India, Chem. Ser.*, 3 (1913), No. 3, pp. 65-106, pls. 7, fig. 1; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 24, p. 1165; *Nature* [London], 92 (1914), No. 2307, p. 564; *Chem. Abs.*, 8 (1914), No. 4, p. 772).—Investigations of the gases in swamp rice soils to determine their composition and relation to manuring and crop growth led to the following conclusions:

The normal fermentation of green manure in swamp paddy soils produces a relatively large proportion of methane, a smaller amount of nitrogen, and some carbon dioxide and hydrogen. The introduction of a crop so modifies the gas production as to reduce the proportions of methane and hydrogen and increase that of nitrogen. The restrictive action of crop growth on methane and hydrogen formation is due to retardation of fermentation or to absorption of a portion of the intermediate products of decomposition by the roots. The retardation of the normal evolution of nitrogen by crop growth indicates that there is an unknown surface evolution of nitrogen not connected with soil fermentation or the surface film which is affected by crop growth.

An anaerobic condition prevailed in the soil immediately after irrigation and throughout the irrigation period, making nitrification impossible and causing

the reduction of the nitrates present. It was concluded, therefore, that the nitrogen required by the crop was obtained from the ammonia and nitrogenous organic compounds produced by the anaerobic decomposition of the proteids of the green manure. Since certain substances so produced are toxic to the crop the application of green manure to poorly drained areas must be undertaken with caution.

Investigations of the gases evolved from the surface of rice soils led to the conclusion that the surface film of algæ, etc., which covers the surface of rice soils evolves a large amount of oxygen which is dissolved by the irrigation water, thus producing a highly aerated solution from which the roots in the soil derive their oxygen. "In undrained soils, this solution does not penetrate into the soil, and, consequently, the roots are congested near the surface of the soil and the amount of soil from which they derive their food is therefore limited and the crop suffers. In drained soils this strongly aerated water penetrates the soil and the roots are able to penetrate to a greater depth. The mass of soil from which the food supply is drawn is increased and the crop benefits in proportion." Too rapid drainage, however, decreases the formation of the surface film so that there is for all swamp paddy soils a comparatively slow optimum rate of drainage. Aeration by atmospheric oxygen is less effective than that by drainage water in promoting root aeration. The use of green manures in drained paddy soils induces a greater activity of the surface film, thus improving root aeration.

The organic constituents of soils (*Rev. Gén. Agron., n. ser., 8 (1913), Nos. 3, pp. 97-103; 4, pp. 145-154*).—This is an appreciative review of investigations by the Bureau of Soils of this Department.

Soil studies by the aid of their water solutions, R. BALLENEGGER (*Földtani Közlöny, 43 (1913), No. 7-9, pp. 359-366*).—Chemical studies are reported of the water solutions of a collection of typical Hungarian soils which were prepared by methods adopted by the Bureau of Soils of this Department (*E. S. R., 17, p. 831*). The soils studied were the gray and brown forest soils, the black clay, black, deep brown and alkaline plain soils, and the aluvial and sandy soils. Water solutions are said to be particularly adapted for the determination of the electrical conductivity.

Ultramicroscopy of soil extracts, S. M. MURAVLIANSKIĬ (*Pochvovîdîenie (Pédologie), 15 (1913), No. 2-3, pp. 23-27*).—Ultramicroscopic investigations of water and ammonia-alkaline extracts of chernozem soils having a variable humus content showed these extracts to be pseudo solutions. In both extracts the cone was more evident, and more submicrons and particles with diffraction rings appeared, the greater the humus content. The alkaline extracts showed a more pronounced cone and a greater number of submicrons than the water extract, while analytical data indicated that mineral constituents are prevalent in the water extracts and organic constituents in the alkaline extracts. It is therefore concluded that the soil colloids generally belong to organic matter.

Microflora of the Roman experimental field, R. PEROTTI (*Staz. Sper. Agr. Ital., 46 (1913), No. 10, pp. 661-668*).—The author discusses the microflora in the soils of this field relative to systems of cultivation, particularly noting the effect of the meteorological elements on their presence and activity and the importance of modifying systems of cultivation accordingly. It was found that the beneficial microbiological functions of this soil are retarded during the hot, dry summer months, while the maximum beneficial activity was found during the winter months, when there was more rainfall and the soil water content was higher.

A study of the formation of nitrates in various types of Virginia soil, E. B. FRED (*Centbl. Bakt. [etc.], 2. Abt., 39 (1913), No. 18-19, pp. 455-468*).—

These investigations have already been noted from another source (E. S. R., 29, p. 621).

Nitrification in acid or nonbasic soils, J. C. TEMPLE (*Georgia Sta. Bul.* 103 (1914), pp. 15).—This is a fuller account of investigations briefly reported elsewhere (E. S. R., 26, p. 722).

The fertility of the soil, E. J. RUSSELL (*Cambridge, England, 1913, pp. VI+128, pls. 10*).—This is one of the Cambridge Manuals of Science and contains "the substance of talks, lectures, and other discourses delivered before all sorts and conditions of men and women and in all kinds of meeting places."

Different chapters treat of the natural history of the soil, how plant food is made in the soil, what soil fertility is and how it may be attained, soil fertility and systems of husbandry, the raising of the fertility limit, the checkered career of the clays, the rise of the sands, and the moor and its management. A brief concluding chapter sums up the general conclusions to which the preceding chapters lead. Here it is shown that while the main purpose of this book is to deal with the problem of making the soil fertile by modifying it to suit the needs of crops, the author is not unmindful of the great importance of modifying crops (by breeding) to suit the soil or of selecting crops especially suited to the soil and climatic conditions.

The increase of plant food in soils, C. T. GIMMINGHAM (*Chem. World*, 2 (1913), No. 12, pp. 376, 377).—On the basis of previous investigations by Russell and Hutchinson (E. S. R., 29, p. 122), it is stated that without doubt the harmful factor which limits the number of plant-food producing soil bacteria, is living, and "the assumption that it is the active soil protozoa fits in with all the known facts."

Preliminary tank experiments on the movement, changes in composition, and toxic effect on wheat of certain salts in sandy loam and adobe soils, R. F. HARE ET AL. (*New Mexico Sta. Bul.* 88 (1913), pp. 32, figs. 7).—The experiments reported were made in tanks filled with sandy loam and heavy adobe soils. Galvanized iron cylindrical tanks 8 ft. high and 8 in. in diameter with 15½ in. holes 6 in. apart from top to bottom were used. The cylinders were filled to within about 4 in. of the top with the soils mixed with varying proportions and combinations of sodium chlorid, sulphate, carbonate, and bicarbonate. The tanks were irrigated from time to time and samples of soil taken for examination at different depths through the holes in the sides of the tanks, the space left by the removal of the sample being filled with the original mixture of soil and salt and the holes kept tightly closed. Some of the tanks were left bare and others cropped to wheat.

The results are discussed in detail. They indicate in general "that the same treatment of sodium chlorid and sodium sulphate in adobe soil leached the chlorid to a crop tolerance limit of 32 in., while the sulphates were not carried beyond 2 in. On sandy loam the chlorids were leached to 80 in. and the sulphate to 38 in. In other words, nearly as much water was necessary to leach the sulphates from sandy loam as was required to remove the chlorids to the same depth in adobe.

"[Apparently sodium carbonate and bicarbonate] may move with the water by capillarity more than the other two salts. The possible change of either one of the salts into the other, as well as the neutralizing effect of gypsum in both soil and water, makes it difficult to compare the leaching action of water on these salts with those of sodium sulphate and sodium chlorid. At the end of the experiment the crop tolerance line of the carbonates and bicarbonates had apparently moved down 20 in. in the adobe soil and to 38 and 44 in., respectively, in the sandy loam.

"Only 0.2 per cent of sodium bicarbonate was added to the soil, and as this amount was fixed as the limit of crop tolerance, no leaching would be necessary to reach this point if it were not for the ready change of the 0.8 per cent of sodium carbonate to the bicarbonate form.

"The results of this experiment would seem to indicate that sodium carbonate and bicarbonate were more easily leached from sandy loam and clay soils than sodium sulphate, and almost equal to sodium chlorid, but the lowering of the tolerance limit of the carbonates and bicarbonates . . . was doubtless due more to reactions with other salts than to the leaching action of the water. This is indicated by the fact that carbonates and bicarbonates were never found concentrated at the lower limits of moisture as were the chlorids and sulphates."

Oat sick land, A. T. FOWLIE (*North of Scot. Col. Agr. Expt. Leaflet 28 (1913), pp. 97, 98*).—Attention is briefly called to certain lands on which oats refused to grow, and it is suggested that this condition is due to alkalinity resulting from the use of large amounts of seaweed. It was found that the application of ammonium sulphate in large measure corrected the unfavorable condition.

[**Unproductive peat or muck soils**], **A. T. WIANCKO** (*Indiana Sta. Rpt. 1913, pp. 60, 61*).—Certain unproductive peat soils which were well supplied with lime, but which did not respond to applications of potash and phosphates, were found to contain 4.375 parts per million of nitrates and total soluble salts amounting to 1.2 per cent. These soluble salts were largely concentrated in the surface soil and probably account for the unproductiveness of the soil and for the death of corn and onions when an attempt was made to grow these crops on the soil. Further proposed experiments with these soils are briefly referred to.

The reclamation of an unproductive soil of the Kankakee marsh region, J. B. ABBOTT, S. D. CONNER, and H. R. SMALLEY (*Indiana Sta. Bul. 170 (1913), pp. 329-374, figs. 22*).—In the experiments here reported it was found that certain restricted areas of peaty sand and dark sandy loam, aggregating perhaps 50 square miles in the Kankakee area in northwestern Indiana, were extremely unproductive even after thorough drainage and liberal manuring and fertilization.

Chemical analyses showed that the soils were fairly well supplied with plant food, but excessively acid; nevertheless the soils contained large amounts of nitrate nitrogen during the growing season. The nitric acid was found to be, in part at least, combined with aluminum, and the apparent acidity of water extracts of the soil was directly proportional to the amount of aluminum present in the solution. Evidently it represented the amount of alkali required to precipitate the aluminum rather than actual free acidity. Application of pulverized limestone rendered the soil productive but did not seem to accelerate greatly the already rapid rate of nitrification. "The evidence indicates that some element in these soils other than calcium or magnesium acts as a salifiable base capable of supporting nitrification, and the composition of the water extract of the untreated soil points strongly to aluminum."

It was found that very dilute solutions of aluminum nitrate were toxic to corn seedlings in water culture in the presence of mineral nutrients, the toxicity being approximately equal to that of nitric acid of the same normality and to that of cold water extracts of the unproductive soil containing the same amounts of aluminum and about the same amounts of mineral nutrients.

"The extreme toxicity of aluminum nitrate in water cultures, even in the presence of nutrients, together with the presence of large amounts of water soluble nitrate and aluminum in the soil, leads to the conclusion that soluble salts of aluminum, or more fundamentally, the lack of basicity which permits

them to exist, are largely responsible for the unproductiveness of the soil in question."

The toxicity is overcome and the soil rendered productive by adding compounds such as those of calcium, which possess the common property of precipitating the aluminum and at the same time forming nontoxic salts with its acid radical.

"Application of pulverized limestone or slaked lime at the rate of 2 to 4 tons per acre, supplemented by fertilization with phosphates and potash, has proved effective in field trials on a large scale and is recommended as a practical remedial treatment for rendering this type of soil productive."

The law of minimum, K. VON RÜMKEK (*Fühling's Landw. Ztg.*, 62 (1913), No. 21, pp. 772-774).—The author maintains that the law of minimum applies not only to the external crop and culture relations but also to the racial performance of cultivated crops.

The influence of fertilizing on the resistance of grain to hail, GAUL (*Deut. Landw. Presse*, 40 (1913), No. 104, p. 1252).—Rye, unfertilized or fertilized with manure, showed a poorer stand and was less resistant to hail than that fertilized with superphosphates and kainit. Rye fertilized with nitrogen was strongly developed and showed great resistance, and in this respect ammonium sulphate appeared to give stronger and more resistant straw than sodium nitrate. Kainit also strengthened the straw and increased resistance.

A brief account of trials with lime fertilization, P. BOLIN (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 80 (1913), pp. 7; *K. Landtbr. Akad. Handl. och Tidskr.*, 52 (1913), No. 4, pp. 282-286).—In field trials during the season of 1911-12, lime was applied with sodium nitrate, Thomas slag and potash salt, farm manure, and farm manure with Thomas slag and potash salt, to green oats and hay.

The lime applied with artificial fertilizers did not produce any beneficial effect over that of artificial fertilizers alone, but increased the yields obtained in a marked manner when it was applied with farm manure, or with farm manure and artificial fertilizers. This was especially true in the case of the plats that had received lime (and manure) the preceding year. The favorable results obtained with lime and manure are attributed to the beneficial effect of the lime on the utilization of the nitrogen in the farm manure.

Lime-magnesia fertilizers, E. MABRE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 47, pp. 657-664).—In field experiments on different soils the yields were generally profitably increased by the use of a fertilizer containing 43 per cent of lime and 30 per cent of magnesia, the results being especially favorable when the fertilizer was used in connection with Thomas slag.

Lime-magnesia ratio in the cultivation of grain, F. PISCIOTTA (*Staz. Sper. Agr. Ital.*, 46 (1913), No. 10, pp. 643-660).—Analyses of 60 Italian soils showed a wide variation in the lime-magnesia ratio, due principally to the variation in the lime. It was equal to 1 in only 1 soil and less than 1 in 4 soils. The addition of 40 lbs. of magnesium sulphate per acre to soils increased the grain yield, when added at the time of seeding, sufficiently to offset the expense of fertilization and yield a good net profit. When the magnesium salts were added in the spring, the profit was very small or negative. The best yield was obtained in soils with a high lime-magnesia ratio, but contrary to the theory of Loew a profitable increase was also obtained in soils having a lime-magnesia ratio less than unity.

Sponges as a fertilizer, J. G. SMITH (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 10, p. 850).—It is stated that sponges, which grow in enormous quantities in the shallow waters of southern Florida, are used with good results as a fertilizer.

Analysis shows approximately 4 per cent of nitrogen, 0.75 per cent each of potash and phosphoric acid, 5 per cent of lime and magnesia (mainly the former), and 40 per cent of organic matter in the air-dry loggerhead sponge, indicating a high fertilizing value.

Composts, R. D. ANSTEAD (*Planters' Chron.*, 8 (1913), No. 51, pp. 654-655).—About 24 tons of materials consisting of alternate layers of coffee pulp (E. S. R., 28, p. 224), ashes, and bone meal were placed in brick pits and allowed to rot down to about 15 tons of compost ready for application. This contained 68.8 per cent of water. The air-dry compost contained 4.34 per cent of phosphoric acid, 0.76 per cent potash, 5.89 per cent lime, and 1.96 per cent nitrogen.

Fertilizers in Japan, W. GASSETT (*Daily Cons. and Trade Rpts.* [U. S.], 17 (1914), No. 7, p. 109).—The total value of fertilizers consumed in Japan in 1912 is stated to have been \$104,425,093, of which \$30,617,500 was for artificial fertilizers, \$32,300,000 for night soil, \$31,410,000 for taibi (manure from straw, etc.), and \$7,057,500 for ryokubi (green manure (?)) and other kinds.

The value of imported manures was over \$26,000,000, including bean cake \$12,650,000, rape-seed cake \$1,300,000, cotton-seed cake \$500,000, ammonium sulphate \$7,500,000, phosphate \$3,150,000, and sodium nitrate \$1,400,000.

"Alaskan powdered fish manure has been imported for some years as a substitute for Hokkaido fish manure, but owing to the bad quality none was imported into Kobe in 1912. This year (1913) the quality has been improved, some shipments have been made, and there is a good demand for it at the present price, about \$2.15 per 10 kwan (about \$2.50 per 100 lbs.).

"The Japanese in Chosen recently have been using starfish as fertilizing material; it is reported to be excellent for rice. An analysis shows it to contain 4.858 per cent nitrogen and 0.889 per cent phosphoric acid. The price is about half that of Japanese-made oil cake."

Report of analyses of samples of commercial fertilizers collected by the Commissioner of Agriculture during 1913 (*New York State Sta. Bul.* 371 (1913), pp. 433-548).—Analyses of samples of fertilizers and agricultural lime collected and examined under the provisions of the New York State fertilizer law during 1913 are reported with a schedule of trade values of fertilizing materials and a brief discussion of the valuation and agricultural value of fertilizers.

AGRICULTURAL BOTANY.

Introduction to botany, J. Y. BERGEN and O. W. CALDWELL (*Boston, New York, Chicago, and London, 1914*, pp. VII+368, pl. 1, figs. 246).—This book, which is an abridgment of the authors' *Practical Botany* (E. S. R., 27, p. 423), is designed for half-year courses in elementary schools. The order of treatment adopted is to give a general notion of the distribution and importance of plants and to describe the plant as a working machine, discussing its structure and work, after which some of the greater groups are briefly presented. Throughout the entire work the plants used as a basis of study are usually those of common interest. A few of the more practical applications, such as timber and forestry, weeds, plant breeding, and the plant industries, are given separate chapters.

Popular botany: The living plant from seed to fruit, A. E. KNIGHT and E. STEP (*New York, [1913], vols. 1, pp. VIII+288, pls. 9, figs. 351; 2, pp. 289-588, pls. 9, figs. 370*).—This book tells in a popular manner of the salient features of plant life, the object being to awaken an interest in the plant world and to stimulate the reader to investigate facts for himself.

Plant life and plant uses, J. G. COULTER (*New York, Cincinnati, and Chicago, 1913*, pp. XVI+464, pl. 1, figs. 230).—This is an elementary text-book

designed as a foundation for the study of agriculture, domestic science, or college botany. It is intended to give the fundamentals regarding plant life in such a manner as to arouse an interest in plants and an appreciation of their rôle in organized life. The style is simple and direct, leading the young student gradually to the more complex problems, which are presented in a very simple manner. Exercises are appended to the various chapters, and by judicious selection the teacher should be able to give his pupils a fairly adequate knowledge of the principal facts regarding the plants of any locality.

The useful plants of the Dutch East Indies. K. HEYNE (*De Nuttige Planten van Nederlandsch-Indië*. Batavia: Dept. Landb., Nijr. en Handel, 1913, vol. 1, pp. 250+XXVII).—In this work the author describes the principal economic plants occurring in the Dutch East Indies and gives a synoptical catalogue of the collections in the technical museum at Buitenzorg. Detailed notes are given on the occurrence, distribution, parts used, methods of preparation, culture, commerce, etc. The present volume includes the genera and species of the families from Cycadaceæ to Orchidaceæ.

Northwest flora. T. C. FRYE and G. B. RIGG (*Seattle, Wash.* [1913], pp. 453).—This manual includes the flowering plants only and covers the States of Washington, Oregon, and Idaho, and the southwestern portion of British Columbia. Keys are presented, based as far as possible on easily determined characters, by which it is thought it will be possible for the student to recognize without difficulty the plants in the region included.

Attempts to grow mistletoe on monocotyledons and succulent conservatory plants. E. HEINRICHER (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl.*, 121 (1912), I, No. 7, pp. 541-572, pl. 1, figs. 12).—This is a fuller account of studies noted previously from another source (*E. S. R.*, 29, p. 352).

Ripening and rest period of mistletoe seeds and conditions influencing germination. E. HEINRICHER (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl.*, 121 (1912), I, No. 7, pp. 573-613, fig. 1).—Reporting a further study of the germination relations of *Viscum album* (see above), the author states that seeds of ripe mistletoe berries from plants cut early and hung in open shaded situations in October germinated readily in late fall and winter, but not in spring, while those of live plants preserved their germinability all winter. Indoor culture shortened both the rest period and germinating period of the seeds, preserving their full germinability. Toward the red end of the spectrum both germinability and subsequent growth were favored, while toward the violet end many seeds were killed before germination. Moisture and temperature seemed to affect germination by influencing the activity of bacteria and fungi present in the slime secretion which secures adhesion of the seeds to the host plant.

The rôle of acids in germination. GERMAINE PROMSY (*Du Rôle des Acides dans la Germination*. Thesis, Univ. Paris, 1912, pp. 177, pl. 1, figs. 11).—The author presents a detailed account of her investigations on the rôle of acids in the germination of seeds, some of the results of the investigation having been noted elsewhere (*E. S. R.*, 27, p. 729; 29, p. 26).

The author has found, from her study of a large number of seeds, that germination is favored by weak acidity in the medium, especially of those seeds which are from fleshy acid fruits. An investigation of these fruits during their decomposition showed that their acidity did not exceed the degree found most favorable to the germination of their seeds. The organic acids favor an increased dry weight in seedlings more than the mineral acids. Salts of the stronger acids induced turgescence, but did not increase dry weight.

The medium in which the seedlings were grown was found to bear an important rôle in the experiments. Knop's solution always showed an antag-

onistic action toward the acids. It is thought that the action of the acids could be explained by the possibility that they transform zymogens in the seed into active ferments and at the same time attack some of the reserve materials in the seed, such as the starch.

The principal modifications in the anatomy of the seedlings due to the acids are said to be a retardation in the thickening of the supporting tissues, greater size of the central cylinder, and an increase in the conducting tissues.

The influence of light on seed germination and its dependence upon other factors, H. BAAR (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 121 (1912), I, No. 7, pp. 667-705, figs. 4*).—The author reports that germination of seeds of *Amarantus* was hindered by light, a tender age of the seeds generally increasing their sensitivity. The maximum limitation was noted at temperatures between 10 and 5° C. *Physalis franchetti*, which germinated better in light than in darkness at 35 to 15°, gives a better response to darkness than to light at 15 to 5°. The substratum is said to be of more importance in this connection in case of the lower temperature. Germination of fresh seeds of *Clematis vitalba* at low temperatures is favored by darkness, that of older seeds by light. Seeds of *Begonia semperflorens* germinated better in light.

A bibliography is appended.

A first study of the relationship between the weight of the bean seed, *Phaseolus vulgaris*, and the time required for its germination, J. A. HARRIS (*Plant World, 16 (1913), No. 10, pp. 267-274, figs. 2*).—From the data obtained in a series of experiments with *P. vulgaris*, the author finds that as the weight of the seed increases the time required for germination becomes longer.

Alcohol formation by sprouting wheat, S. KOSTYTSCEW and A. SCHELOUMOFF (*Ber. Deut. Bot. Gesell., 31 (1913), No. 8, pp. 422-431*).—The authors state, in regard to living wheat sprouts, that they form with complete aeration no alcohol. In the presence of toluol, the formation of alcohol is only 3 per cent of carbon dioxid, but with incomplete aeration, 50 per cent as much as that of carbon dioxid. With living embryos all of the carbon dioxid formed is thought to be referable to normal respiration, with those not capable of growth only half.

The respiration of living and of killed wheat seedlings, S. KOSTYTSCHEW, W. BRILLIANT, and A. SCHELOUMOFF (*Ber. Deut. Bot. Gesell., 31 (1913), No. 8, pp. 432-441*).—It is stated that an apparently slight limitation of the air decreased considerably the amount of oxygen taken up into both living and dead roots of wheat. While certain phosphates exert no perceptible influence upon the production of carbon dioxid and the absorption of oxygen by living wheat embryos, fermented sugar solutions increased both proportionately in the case of living plantlets. Dead plants showed an increase of carbon dioxid only.

The influence of location on leaf development of *Ipomœa pes-capræ*, Z. KAMERLING (*Rec. Trav. Bot. Néerland., 10 (1913), No. 2, pp. 147-152, figs. 2*).—Comparative measurements of leaves of *I. pes-capræ* grown on open coasts with those grown in partial shade are cited to show that while development in the apical portions (which is completed relatively early) is much the same in both situations, development of other portions of the leafblade and of the petiole is very much greater in case of partially shaded plants.

Is there a mutual stimulation of plants through root influence? T. L. LYON and J. A. BIZZELL (*Jour. Amer. Soc. Agron., 5 (1913), No. 1, pp. 38-44*).—Experiments in growing different plants on the same area at the same time are held to show that a number of common agricultural plants named, such as wheat and mustard, timothy and red clover, barley and buckwheat, and peas and lettuce, are advantageous to each other when grown on the same ground.

Secretion by roots of substances toxic to the plants, M. MOLLIARD (*Bul. Soc. Bot. France, 60 (1913), No. 5, pp. 442-446*).—Comparison of the develop-

ment attained by peas furnished with distilled water with that attained by those furnished with aerated water is said to support the hypothesis that substances are formed by growing roots which are toxic to plants of the same species.

The root nodules of the Podocarpeæ, W. B. BOTTOMLEY (*Abs. in Rpt. Brit. Assoc. Adv. Sci., 1912, p. 679*).—Discussing the functions of the root nodules of the several genera in connection with their structure as described by Miss Ethel R. Spratt (*E. S. R., 27, p. 828*), the author states that the bacterial tissue of the nodule continues functional as such for one year only, being pushed out in the following spring to form in connection with older layers an outer protective zone, the outermost layer of which remains intact except in case of the bifurcated nodules of *Saxegothea*.

The function of calcium in plants, K. FAACK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien, 2 (1913), No. 1, pp. 175-207*).—Presenting the results of a study on the influence of calcium and related elements separately and together on plants, the author states that the injurious effects of a calcium-free medium are due to its extraction of calcium from the plant organs, which by inner supply with calcium may be protected from such injury; that high concentrations of strontium without calcium influence plant growth unfavorably; that by supplying sufficient calcium with strontium the injurious effects of the latter are lessened or prevented; that while strontium in part takes the place of calcium, permitting limited development, its influence is partial and temporary, only deferring the exhaustion of the plant; and that strontium does not appear to influence the distribution of carbohydrates or the localization of that process. A bibliography is appended.

The inutility of zinc in the culture of *Aspergillus niger*, C. LEPIERRE (*Compt. Rend. Acad. Sci. [Paris], 157 (1913), No. 19, pp. 876-879*).—In continuance of previous reports (*E. S. R., 29, p. 628*), the author states that while under certain conditions zinc exerts a favorable influence on growth of *A. niger*, its presence is not indispensable to the complete development of this fungus. Apparent exceptions are probably due to a lack of purity in the materials employed.

Inutility of zinc for culture of *Aspergillus niger*, C. LEPIERRE (*Bul. Soc. Chim. France, 4. ser., 13 (1913), No. 24, pp. 1107-1121*).—Continuing the above discussion of his own work, in connection with the results and views of others, the author holds that the undeniable utility of zinc in certain concentrations for the culture of *A. niger* is not to be confounded with the indispensability thereof, as held by some authors mentioned.

Zinc and *Sterigmatocystis nigra*, H. COUPIN (*Compt. Rend. Acad. Sci. [Paris], 157 (1913), No. 25, pp. 1475, 1476*).—Noting recent observations of his own in connection with the reports and views of Lepierre (see above), considered by Javillier to be inconsistent with the results of his own experiments (*E. S. R., 20, pp. 28, 831*), the author concludes that the results of his own work and that of the former author are reciprocally confirmatory.

Zinc and *Aspergillus*, C. LEPIERRE (*Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 1, pp. 67-70; abs. in Rev. Sci. [Paris], 52 (1914), I, No. 3, p. 94*).—Repeating the experiments of Coupin and Javillier (above noted) under the original conditions, so far as possible, the author concludes that the differences noted, which were apparent also in his experiments, may be due to differences in conditions of aeration, etc.

Osmotic pressures in plant organs.—III, The osmotic pressure and electrical conductivity of yeast, beer, and wort, H. H. DIXON and W. R. G.

ATKINS (*Sci. Proc. Roy. Dublin Soc., n. ser., 14* (1913), No. 2, pp. 9-12; *Notes Bot. School Trinity Col. Dublin, 2* (1913), No. 4, pp. 173-176).—In continuance of studies previously reported (E. S. R., 29, p. 828), the authors found that in both osmotic pressure and electrical conductivity pressed yeast gives values much higher than those of wort. Bakers' yeast, however, gave a low osmotic pressure but a high conductivity even after washing. On comparing the results given by beer with those of wort, it was noted that while the electrical conductivity remains much the same, the osmotic pressure becomes approximately three times as great during fermentation, when interrupted at the usual stage in the commercial process. Very complete fermentation, however, in the single experiment carried out, occasioned a fall in osmotic pressure after the initial rise and was accompanied by a marked increase in conductivity.

Studies on the influence of electricity on plant growth, W. SCHIKORRA (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 5* (1913), No. 5, pp. 403-411, fig. 1).—Tests with an electrical brush discharge of high tension on the development of several cereals are reported to show no very decidedly beneficial effects on growth. The results reported by P. Vozáry (E. S. R., 28, p. 326) are thought to be due largely to an increase of transpiration by the electrical wind attending the brush discharge.

Influence of radio-active emanations on vegetation, J. STOKLASA and V. ZDOBNICKY (*Compt. Rend. Acad. Sci. [Paris], 157* (1913), No. 22, pp. 1082-1084).—Presenting some quantitative results of a study with several grains, legumes, etc., subjected to radio-active energy from different sources, the authors state, in conclusion, that radio-active emanations in moderate concentrations influence favorably the development of plants and gaseous exchange thereby, their flowering, and total production. Very heavy concentrations, on the contrary, check the development and appear to cause or favor the formation of toxic substances in the chlorophyll bearing portions.

Influence of radio-activity on micro-organisms which fix nitrogen or transform nitrogen compounds, J. STOKLASA (*Compt. Rend. Acad. Sci. [Paris], 157* (1913), No. 19, pp. 879-882).—This is a study of several nitrifying and denitrifying bacteria in varied nutritive solutions subjected to the action of emanations from pitchblende. The results are thought to show a considerable influence of radio-activity upon the general circulation of nitrogen and to be of importance in connection with the control of soil fertility.

The study of cold resistance by cereals, G. GASSNER and C. GRIMME (*Ber. Deut. Bot. Gesell., 31* (1913), No. 8, pp. 507-516).—In tests with barley and rye it was found that the varieties germinating at the lower temperatures showed the higher sugar content, but no other marked differences of composition. Winter injury to green plants is attributed to volumetric alterations rather than to any peculiar effect on the plant cells.

The blackening of the leaves of *Aucuba japonica*, S. G. PAINE (*Abstr. in Rpt. Brit. Assoc. Adv. Sci., 1912*), pp. 439, 440).—Experimental evidence cited is claimed to show that not only anesthetics but a variety of other agencies produce the blackening of leaves studied in *A. japonica*. It is stated that the only character common to these agencies is not that they are activators of enzymes but that they tend to produce death of the tissues. The blackening is held to be a result of changes of permeability whereby enzymes more readily pass into the tissues, as claimed by Maquenne and Demoussy (E. S. R., 23, p. 131).

Studies on photosynthesis, K. PURIEWITSCH (*Jahrb. Wiss. Bot. [Pringsheim], 53* (1913), No. 2, pp. 210-254, figs. 18).—The utilization rate of the leaves (so far as tested) for incident solar energy as related to photosynthesis was found to vary from 0.6 to 7.7 per cent. The average rate shown by *Acer platanoides* was 1.3 per cent and that by *Polygonum sachalinense* 3.6 per cent.

FIELD CROPS.

Cultivation of crops, M. HOFFMANN and A. KOSTLAN (*Jahresber. Landw.*, 26 (1911), pp. 105-216).—Recent German publications of investigations on this subject are classified and reviewed.

Addresses on plant breeding (*Beitr. Pflanzenzucht*, No. 3 (1913), pp. VIII+216, figs. 45).—This publication gives the proceedings of the third annual meeting of the Society for the Promotion of Plant Breeding in Germany, and the following addresses with discussions: Rye Breeding, by K. von Rümker; Some Practical Results in Recent Hybridization Work, by E. Baur; Unusual Cereal Hybrids, by E. von Tschermak; Winter Wheat Work at Svalöf Farm, 1900-1912, by H. Nilsson-Ehle; The Production of Elementary Varieties from Hybridization with Mendelian Segregation, by F. Rosen; The Technique of Grass Breeding, by Fruwirth; The History of Germination with the Sugar Beet, by R. Schander; The Application of Probable Error Formulas in Plant Breeding Manipulations, by H. Quante; and Sex-limited Inheritance in the Animal Kingdom, by F. Pax.

The storage of vegetable products of agriculture, A. GRÉGOIRE (*Rev. Écon. Internat.*, 10 (1913), II, No. 2, pp. 444-459).—This article surveys the work done in this field on hay, silage, and grain, and discusses the resulting chemical, bacterial, and other changes that take place and the effect on the value of the product.

[Experiments with field crops], F. WATTS ET AL. (*Imp. Dept. Agr. West Indies Rpts. Bot. Sta. [etc.] Antigua, 1911-12*, pp. 6-21).—In continuation of work previously noted (E. S. R., 26, p. 733), this reports the results of experiments in progress with sweet potatoes, broom corn, cotton, yams, sesame, green manures, Jerusalem peas (*Phaseolus trinervis*), pigeon peas, cowpeas, Dwarf Essex rape, castor beans, onions, peanuts, and soy beans. A report is given of special work which is being carried on in the selection and hybridization of cotton.

Report on the botanic station, St. Kitts-Nevis, 1911-12, F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Bot. Sta. St. Kitts-Nevis, 1911-12*, pp. 34).—In continuation of earlier work (E. S. R., 26, p. 534), this report gives the results of experiments in hybridizing cotton, and varietal and manurial trials with sweet potatoes, yams, tobacco, cassava, peanuts, pineapples, Guinea corn, onions, Indian corn, and sugar cane.

Annual report of the demonstration farm, St. Andrew's Colonial Homes, Kalimpong, for the year 1911-12 (*Ann. Rpt. Kalimpong Demon. Farm [India] 1911-12*, pp. II+25).—This report gives notes on trials of varieties of maize, rice, millet, buckwheat, wheat, barley, cotton, and legumes.

Annual report of the Rajshahi Agricultural Station for the year 1911-12 (*Ann. Rpt. Rajshahi Agr. Sta. [India], 1911-12*, pp. 7).—This reports experimental work with winter rice, jute, and sugar cane. In spacing winter rice it was found that 2 or 3 plants per hill, and the hills 8 in. apart in the row, gave better results than 1 or 4 plants per hill or hills spaced 10 or 12 in. apart.

Annual report of the Rangpur Farm for the year 1911-12 (*Ann. Rpt. Rangpur Farm [Bengal], 1911-12*, pp. 10).—This report gives brief notes on variety tests of millet, potatoes, sugar cane, jute, and rice.

Fodder plants of Java, I and II, C. A. BACKER (*Teysmannia* 23 (1912), No. 2, pp. 102-112, pl. 1; 24 (1913), No. 4, pp. 209-229).—This article treats of the history and botanical description of *Sesbania grandiflora*, *Artocarpus integrifolia*, and the various species of *Paspalum*, discusses their cultivation and value, and gives chemical analyses, coefficients of digestibility, and yields.

Native permanent meadow v. seeded meadow, SCHUBERT (*Wiener Landw. Ztg.*, 63 (1913), No. 18, pp. 211-213, figs. 12).—In experiments conducted during 1911 and 1912 the superiority of the seeded areas showed in the marked improvement in the quality of the hay and also in the yields, which increased from 83 to 175 quintals per hectare (3.7 to 7.8 tons per acre) in 3 cuttings in 1912.

On the manuring of meadow hay, J. PORTER (*Herefordshire County Council Sub. Farmer's Bul.* 5 (1910), pp. 6).—The use of sulphate of ammonia alone apparently favored the growth of the grasses, while phosphate and potash favored the growth of legumes and depressed that of the grasses. Lime was followed by a net increase in hay yields. The omission of phosphates resulted in a greater loss in yields than the omission of either nitrogen or kainit. "The most successful dressing used in the experiment was a medium dressing of farmyard manure (10 tons) in alternate years, and during those years receiving no farmyard manure a mixture of 102 lbs. sulphate of ammonia and 352 lbs. superphosphate." The 5-year average of hay yields per acre ranged from 27 cwt. without fertilizers to 37.5 cwt. with a complete fertilizer which consisted of 102 lbs. sulphate of ammonia, 60 lbs. sulphate of potash, and 352 lbs. superphosphate per acre.

Trials in seeding cereals in hills, J. DUMONT (*Ann. École Nat. Agr. Grignon*, 2 (1911), pp. 59-62).—Harrowing and rolling were followed by larger yields with wheat than rolling alone, whether the seed was drilled with 18 cm. (about 7 in.) between drills, or planted in hills 10 by 25 cm., 1 kernel per hill, or in hills 20 by 25 cm. with 2 kernels per hill. In another similar group of plats hoed and weeded the yields were still further increased. The wheat planted 10 by 25 cm. with 1 kernel per hill gave the best results in each case.

A study on causes of the difference in drought resistance between clover and alfalfa, W. SHOLTKEWITSCH (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 3, pp. 167-180, figs. 4).—In a study of the movement of water in these plants, the relation of transpiration between clover and alfalfa stood as 100:163 and the length of the stomata as 100:156. The pith occupied relatively less of the cross section of the stem in alfalfa than in clover, but the number of xylem bundles was proportionately increased. The diameters of these vessels were also larger than those of clover and allowed from 4 to 4.5 times as much water to pass through them.

Agave in the West Indies, W. TRELEASE (*Mem. Nat. Acad. Sci.*, 11 (1913), pp. 299, figs. 227).—The author gives in tabular form an analysis of the geographical distribution of agave in the West Indies, and discusses the specific characters of the trunk, leaves, flowers, fruit, and bulbils. A synopsis is followed by botanical descriptions of 8 groups including 56 species.

Three-year results with Turkestan alfalfa, J. GYÁRFÁS (*Kísérlet. Közlem.*, 16 (1913), No. 3, pp. 405-408).—These results showed Turkestan alfalfa to be inferior to Hungarian alfalfa at the Magyar Ovar station.

Experiments with a new form of barley, E. SCHNEIDER (*Ztschr. Pflanzenzücht.*, 1 (1913), No. 3, pp. 301-322, figs. 3).—This describes a new form of barley that appeared in Posen in 1902, the chief feature of which was a branching of the spikes. This characteristic proved to be transmitted with constancy. The yield was somewhat in excess of the ordinary varieties, but the quality was inferior.

Thermotoxy, or factors in the growth of cotton in Egypt, W. L. BALLS (*Rpt. Brit. Assoc. Adv. Sci.*, 1912, p. 682).—The author here notes the complete arrest of growth in the bud of Egyptian cotton when the day temperature reaches 35° C. (95° F.) for successive days, due, probably, to toxins being more rapidly secreted than dissolved, on account of a suspension of growth processes.

Different species of *Gossypium* differ greatly in their liability to this poison under the same conditions without any relation to their temperature acceleration of growth. Hybrids therefore showed most various growth relationships in F_2 and there were indications that a Mendelian segregation may be found.

The culture of cotton in Egypt, AHMED EL ALEI, trans. by A. SEBBAGH and C. LÉPINEY (*Dir. Gen. Agr., Com. et Colon. [Tunis], Mem. et Docs., No. 6 (1913), pp. 11+134, figs. 2*).—The 3 parts of this book treat of the cultivation and seed production, diseases, and insect enemies of cotton, and general observations on the industry in Egypt, and also include statistical data.

The relation of cotton buying to cotton growing, O. F. COOK (*U. S. Dept. Agr. Bul. 60 (1914), pp. 21*).—This bulletin contains discussions and suggestions under the following headings: The need of discrimination in buying; varieties deteriorate by losing uniformity; careful farmers deserve the higher prices; discrimination in buying more important than high prices; development of new long-staple districts; commercial causes of deterioration of cotton; deterioration of the Sea Island cotton crop; limitations and injustice of the present system of buying; uniformity best determined by field inspection; field inspection in the interest of manufacturers; other causes of uneven fiber; and economic peculiarities of the cotton industry.

Tests of the waste, tensile strength, and bleaching qualities of the different grades of cotton as standardized by the United States Government, N. A. COBB (*U. S. Dept. Agr. Bul. 62 (1914), pp. 8, fig. 1*).—This is a report of progress upon some spinning tests that are being made at about a dozen cotton mills in the United States to determine qualities of cotton fiber that may be used in fixing market grades.

Some results obtained thus far show the average difference in percentage of visible waste between "Western upland" and "Atlantic States upland" to be between 1 and 2 per cent. Preliminary tests show the yarn from the two classes of cotton to be about equal in strength. The mill waste in the experiments to date varied from about 4 per cent in "middling fair" to about 11 per cent in "good ordinary" cotton.

Elephant grass, O. STAFF (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 7 (1912), pp. 309-316; Rhodesia Agr. Jour., 10 (1913), No. 3, pp. 362-368, pls. 3*).—This article gives the history, distribution, vernacular names, uses, and chemical analysis of *Pennisetum purpureum*. It is noted that the analysis indicates a feeding value similar to maize fodder, and a rather high fertilizing value. The plant is a better drought resister and gives larger yields than Paspalum.

Comparison of phonolite meal (potassium silicate) with forty per cent potassium salt in fertilizing hops, F. WAGNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 11 (1913), Nos. 4, pp. 52, 53; 5, pp. 67-70; 6, pp. 77-82, fig. 1*).—The use of 143 kg. of K_2O in the form of 40 per cent salt was followed by an increase in yield of hops per hectare over untreated plats of 763 kg., whereas the same amount of K_2O as silicate (phonolite) showed a gain of 245 kg. Using half the quantities of K_2O , the respective gains were 466 and 92 kg. The largest yield gave the largest net profit per hectare.

Origin and home of the cultivated oats, A. SCHULZ (*Ztschr. Gesam. Getreidew., 5 (1913), No. 5, pp. 139-142*).—In this article the author divides the species into 7 subspecies and discusses the appearance of these in various countries in which they seem native.

Report on oat culture experiments in Saxony, 1910-1912, STEGLICH (*Sächs. Landw. Ztschr., 61 (1913), Nos. 11, pp. 144-148; 12, pp. 161, 162*).—This reports the results of varietal and cultural tests of oats in progress, with special reference to the influence of change of soil and climatic conditions on yields.

The oat kernel, R. A. BERRY (*Rpt. Brit. Assoc. Adv. Sci.*, 1912, pp. 733, 734).—The results from a series of analyses extending over several years are reported.

"By tabulating the grain of over a hundred varieties, according to the percentage and weight of kernel, along with the chemical analyses, it is possible to distinguish several more or less well-defined types. The white grains group into (1) small grains with a thin husk, a high percentage of oil, and an average percentage of nitrogen. These are characteristic of and include the old Scotch varieties with the newer selected strains from same. (2) Large grains fall into 2 groups, viz, a thick husk, a low percentage of oil, and high nitrogen; a thin husk, a higher percentage of oil, and a lower nitrogen. (3) Grains intermediate in character and chemical composition to the large and small include the bulk of the newer hybrid varieties.

"The black grains grade into (1) small grains with a thick husk, low oil, and average nitrogen; (2) medium grains with a thick husk, high oil, and low nitrogen; (3) large grains with a thin husk and the richest kernel of the cultivated oats. These are the winter oats. The reddish and yellow grains form separate groups. The wild oat surpasses all in richness of kernel.

"[Regarding the variation of the kernel,] results show that climate is the most disturbing factor. Distinguishing characters associated with a certain set of climatic conditions become greatly modified and, in some cases, almost obliterated when the conditions are radically changed. . . .

"Micro-chemical tests [with oil and nitrogen] show the oil to be located in the aleurone layer and the embryo. The latter forms from 2.5 to 4 per cent of the kernel, and contains between 11.25 and 12.25 per cent of the oil, and between 4.5 and 6.5 per cent of the protein of the whole kernel. The smaller grains of the same variety are invariably richer in oil but slightly poorer in nitrogen. Analyses made every 3 days during the formation and maturation of the grain show the oil to increase rapidly in the first half, then remain stationary, while the nitrogen increases all through the period."

Irish potatoes in Florida, A. P. SPENCER (*Florida Sta. Bul.* 120 (1914), pp. 83-93, figs. 4).—Cultural methods are given, with special reference to the Spaulding Rose 4 variety on flat-woods land.

Potato culture, A. W. GARDENER (*Cuba Mag.*, 4 (1913), No. 11, pp. 508-511, fig. 1).—This article gives a practical method of producing potatoes in the Isle of Pines, in which the total cost was \$91.20, with a net profit of \$131 per acre.

On the manuring of potatoes, J. PORTER (*Herefordshire County Council Farmer's Bul.* 2 (1910), pp. 4).—These experiments indicated that the omission of potash from an otherwise complete fertilizer is not advisable, as the yields were reduced 26 cwt. per acre. The results were better with sulphate of potash than with the low grade potash manures, and with nitrate of lime than with sulphate of ammonia. The yields ranged from 6 tons 15 cwt. to 10 tons 7½ cwt. per acre.

Experiments in the pollination of rape, K. VON RÜMKE and R. LEIDNER (*Ztschr. Pflanzenzücht.*, 1 (1913), No. 3, pp. 323-327, fig. 1).—From field observations in breeding rape and developing seeds from flower buds isolated in glass tubes, the author concludes that rape is self-fertilizing as a rule but that it may be fertilized by foreign pollen.

Cultural experiments with annual rye grass, AHR (*Prakt. Bl. Pflanzenbau u. Schutz*, n. ser., 10 (1912), No. 10, pp. 113-118).—When Italian rye grass was sown in red clover, the yield of hay was increased only 13.7 kg. per hectare (12.2 lbs. per acre) in 1 case and 350 kg. in another, while with annual rye grass the amount of hay increased 970 and 230 kg. When annual rye grass was seeded alone at the rate of 30, 40, 50, and 60 kg. of seed per hectare, the

yields of hay were 7,480, 7,840, 8,800, and 8,300 kg. per hectare, respectively. These yields were obtained in 3 cuttings.

Comparison in field experiments with **Westerwold, Argentina, and Italian rye grass**, HILTNER, LANG and GENTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 10 (1912), No. 10, pp. 118-124, fig. 1).—The yields in these experiments were with Westerwold 109.5 kg., Argentina 119 kg., and Italian rye grass 128.5 kg. per plat, produced in 2 cuttings each.

The Sansevierias, F. MICHOTTE (*Agr. Prat. Pays Chauds*, 13 (1913), Nos. 122, pp. 356-375; 123, pp. 455-474, figs. 2).—This paper describes the botanical characteristics of this genus of plants, methods of cultivation and propagation, and the climate and soil to which it is adapted, and mentions the countries in which it appears. Methods of extracting the fiber by hand and by machinery are described, and the chemical composition, fiber strength, and uses of the fiber are given.

Bud mutations of tubers as affected by cultural methods with *Solanum tuberosum* and *S. maglia*, E. HECKEL (*Bul. Soc. Nat. Agr. France*, 72 (1912), No. 8, pp. 698-716, pl. 1, figs. 3).—This article gives the results of observations on the manner of variations of *S. tuberosum* and *S. maglia* as influenced by cultural methods, especially by the applications of cow, horse, sheep, and hen manure in varying mixtures.

Sugar-beet growing under irrigation, C. O. TOWNSEND (*U. S. Dept. Agr. Farmers' Bul.* 567 (1914), pp. 26, figs. 5).—This gives directions for sugar-beet culture under irrigation and discusses, with suggestions, the subjects of selection of soil, climatic conditions, plowing, the seed and root beds, drainage, irrigation, holding the moisture, planting the seed, spacing and thinning, cultivating, hoeing, harvesting, crop rotation, fertilizers, live stock, and by-products.

Sugar-beet growing under humid conditions, C. O. TOWNSEND (*U. S. Dept. Agr. Farmers' Bul.* 568 (1914), pp. 20, figs. 4).—This consists of instructions for the production of sugar beets under humid conditions.

Fertilizing sugar beets in the drill, 1912, J. GYÁRFÁS (*Kísérlet. Közlem.*, 16 (1913), No. 3, pp. 367-380, fig. 1).—This reports work in progress in which superphosphate and nitrate of soda, drilled with the seed, seemed to have a beneficial influence on the germination of the seed and development of the young plants.

Nitrate of soda in the cultivation of sugar beets (*Sucr. Indig. et Colon.*, 82 (1913), No. 5, pp. 107-109).—One application of nitrate of soda at seeding time gave larger yields of beets of greater density than when part was applied at thinning time.

Increasing crop production by means of a stimulant, A. STUTZER (*Bl. Zuckerrübenbau*, 20 (1913), No. 14, pp. 209-211).—The author discusses the plant stimulants and gives the results of applying to sugar beets 4 kg. of lead nitrate in a fertilizer furnishing 50 kg. of P_2O_5 , 80 kg. K_2O , and 45 kg. of nitrogen per hectare. An increased yield of 398 kg. from one field and 171 kg. from another was attributed to the use of the lead nitrate.

The nitrogen content of beet sugar and of molasses, E. SAILLARD (*Sci. Agron.*, 30 (1913), No. 1, pp. 27-35).—Tabulated results of nitrogen determinations of numerous varieties covering a period of years in a study of the climatic effects are given.

More total nitrogen was found in a dry year than during a wet year. This nitrogen was in ammoniacal and amid forms rather than in the injurious forms, while the increase of albuminoids was less marked than that of the other forms. It is noted that these results coincide with the increase of albuminoids found in wheat in dry years.

The same was found to be true in regard to molasses. That produced in a dry season, 1911, contained 2.62 per cent of total nitrogen, while in the wet season of 1910 it contained only 2 per cent.

A comparison of some seedling sugar canes with the Bourbon variety in Barbados, J. R. BOVELL (*West Indian Bul.*, 12 (1912), No. 1, pp. 357-360).—The results of trials covering a period of 14 years are given. These indicate a superiority of seedlings B 208 and B 147 over the customary White Transparent of from 6.5 to 24.4 per cent.

Bourbon and seedling canes, J. W. ARBUCKLE (*Dept. Agr. Trinidad and Tobago Bul.* 11 (1912), No. 70, pp. 30-33).—In this article the author discusses the superiority of seedling canes over the old variety, Bourbon, which has practically succumbed to disease.

Sugar cane on savanna lands, R. S. CUNLIFFE (*Cuba Mag.*, 4 (1913), No. 10, pp. 464-470, figs. 6).—Fertilizer trials at Manacas, Cuba, on light soil heretofore considered worthless for sugar-cane culture are reported.

The plat receiving 200 lbs. nitrate of soda, 214 lbs. dried blood, and 416 lbs. basic slag per acre yielded 55,882 lbs. cane, as compared with 10,770 lbs. on the check plat, and an increased profit of \$38.81 per acre. The plat receiving in addition 120 lbs. sulphate of potash yielded 67,973 lbs. per acre, and a profit of \$49.87 over the check plat. The plat receiving 300 lbs. sulphate of ammonia, 170 lbs. double acid superphosphate, and 120 lbs. sulphate of potash yielded 62,106 lbs., and a profit of \$56.02 over the check plat, and the plat receiving in addition to this 400 lbs. nitrate of soda, 170 lbs. double acid phosphate, and 120 lbs. sulphate of potash, yielded 88,576 lbs., and a profit of \$61.50 over the check plat.

Analysis of the cane juice showed for the 5 plats a respective sucrose content of 17.7, 19.12, 18.89, 19.02, and 19.08 per cent, and purity coefficients of 89.65, 89.77, 90.82, 92.78, and 91.29 per cent.

On the manuring of swedes, J. PORTER (*Herefordshire County Council Farmer's Bul.* 4 (1910), pp. 4).—In these experiments, larger yields in general were produced with 6 cwt. of superphosphate per acre than with a combination of 4 cwt. of superphosphate and 2 cwt. of bone flour, or 4 cwt. of superphosphate and 2 cwt. basic slag, but the quality of the roots seemed best with the basic slag mixture. The dressing which gave the greatest yield was $\frac{1}{2}$ cwt. sulphate of ammonia, 6 cwt. superphosphate (30 per cent), and $\frac{1}{2}$ cwt. sulphate of potash. The addition of potash seemed to increase the yield on an average of $18\frac{1}{2}$ cwt. per acre.

The inheritance of certain quantitative characters in tobacco, H. K. HAYES (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 10 (1913), No. 1-2, pp. 115-129, figs. 8).—The author here gives results of continued work (*E. S. R.*, 29, p. 536) on the inheritance of leaf number in F_2 generations of crosses between Sumatra \times Broadleaf and Cuban \times Havana tobacco. The conclusions drawn are as follows:

"Number of leaves per plant is a stable character and little affected by changes of environment. The F_1 generation is of intermediate value, the mean for leaf number being almost exactly equal to the average of the parental means. The F_1 generation is no more variable than the parents. Different variates in F_1 give similar results in F_2 showing the F_1 variation to be of no germinal value. The F_2 generation is much more variable than the parents or F_1 . Some of the F_2 generation breed true in F_3 , giving no greater variability than the parents themselves, others give an intermediate variability between that of the parents and F_2 , and others are as variable as the F_2 generation itself. Intermediates as well as extremes may breed true. Of the 3 F_2 gen-

erations which bred true for leaf number, giving no greater variation than the parents, 2 were intermediates.

"These results give further confirmation of the hypothesis that the inheritance of quantitative characters, such as size, shape, and number of various plant organs may be due to the interaction of a multiplicity of factors, each inherited separately and capable of adding to the character, the heterozygous condition being half the homozygous. The difficulty of determining the number of factors involved is very great, owing to the obscuring effect of fluctuating variability."

A bibliography is appended.

The origin of *Triticum monococcum*, A. SCHULZ (*Ztschr. Gesam. Getreidew.*, 4 (1912), No. 11, pp. 307-309).—Continuing earlier work (E. S. R., 26, p. 827), this article briefly discusses the appearance of 2 subspecies of this plant, one in Europe and the other in Asia.

A Riéti hybrid of wheat, SCHRIBAU (*Bul. Soc. Nat. Agr. France*, 72 (1912), No. 7, pp. 636-640).—A method of producing a hybrid by crossing the Riéti and Japhet varieties of wheat is described. The hybrid proved to be very precocious, awnless, and adapted to the southeastern part of France.

Farmers' experiment plats, H. ROSS ET AL. (*Agr. Gaz. N. S. Wales*, 24 (1913), No. 4, pp. 277-294).—In continuation of work already noted (E. S. R., 27, p. 840), this report gives the results of farmers' wheat experiments, including variety, manurial, and cultural tests in 4 different districts.

Some experiments and observations on the control of [germination of] seeds, H. PIEPER (*Fühling's Landw. Ztg.*, 62 (1913), No. 10, pp. 361-367).—In experiments on the influence of light on the germination of *Poa pratensis* and *Apera spica venti*, exposure to the light during the whole of 7 days gave a higher percentage than any less number of days of light, or than darkness during the entire period. Hulled seed germinated better in both light and darkness than did unhulled seed. With *Lolium westerwoldicum* there was little difference in the germination between seeds that had been swollen in light for 24 hours and those germinated in both light and darkness. With seeds of *P. pratensis* those rubbed out of the panicle germinated better in the darkness than those either pulled out or left intact, while in the light there was practically no difference in the 3 conditions. Both *L. italicum* and *L. westerwoldicum* germinated better on blotting paper in light than in darkness. Barley and spring wheat germinated better in a temperature of from 10 to 12° C. than at 20°.

Wild oats, E. RABATÉ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 32, pp. 166-180, figs. 5).—In a study to determine methods of eradication of this weed and hybrids with cultivated varieties, the author reached the following conclusions: Severe winters tend to decrease its appearance. Deep plowing, with thorough surface cultivation, does much to destroy it during the present season, but favors its appearance in succeeding cereal crops. It is not advisable to sow oats, wheat, or clover on soils that are known to be badly infested with wild oats, but cultivated crops should be planted for at least 2 years, with clean cultivation.

Other less effective methods of combating the weed were hand hoeing, planting in drills to allow of spraying with a 10 per cent solution of sulphuric acid, pulling in April or May, removing the panicles early in June, cutting the crop green, destroying the chaff from the threshed grain, and burning the stubble.

The influence of corn flower (*Centaurea cyanus*) on the harvest of winter rye and barley, A. CHREBTOV (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.)*, 6 (1913), No. 5, pp. 344-348).—In this experiment the plats were sown to vary-

ing quantities of the cereals and weed seed. The largest quantity of weed seed used showed a marked injurious effect on the grain and straw production, causing from one-fourth to one-third decrease in yields.

HORTICULTURE.

Manual of colonial horticulture, A. CHEVALIER, P. TEISSONNIER, and O. GAILLE (*Vég. Utiles Afriques Trop. Franç.*, No. 8 (1913), pp. XXXVII+435, figs. 36).—A popular cultural and descriptive manual of tropical plants and temperate climate plants adapted for culture in the Tropics, including vegetables, fruits, flowers, shrubs, and ornamental trees. A note on the culture of vegetables in the French Sudan, together with a bibliography of general works and special publications on tropical cultures, is appended.

A study of monocotyls relative to the growth of cuttings and grafting, O. SCHUBERT (*Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 13-18, pp. 309-443, figs. 22).—The author here reports in detail a study of asexual reproduction in the superficial organs of monocotyls. The investigation, which was conducted at the plant physiological laboratory at Munich during 1909 and 1910, included the actual propagation of various monocotyls accompanied by a microscopical study of anatomical conditions in the cuttings and grafts, together with a review of the literature on the subject. A bibliography is appended.

In discussing the phenomenon of regeneration the plants are considered according to the nature and mode of their reproduction. The following three types of reproduction by cuttings are recognized: Cuttings in which root formation takes place on the shoot axis itself, either from adventitious roots or from latent roots already present; those in which the roots develop at the base of the side shoots; and those in which roots develop on the leaves. Variations within these types are also considered.

Summing up the past and present results secured in grafting experiments with monocotyls the author concludes that thus far a successful method of grafting has not been evolved.

Has sulphur a direct growth effect on plants? W. JANICAUD (*Gartenwelt*, 18 (1914), No. 3, pp. 29-32, figs. 4).—In pot experiments with tomato plants conducted at the horticultural experiment station at Mülhausen, Alsace, sulphur was used as a fertilizer, both alone and in combination.

As compared with the growth of plants receiving no fertilizer, sulphur used alone at the rate of 2 gm. of flowers of sulphur to 1 kg. of soil appeared to have a somewhat deleterious effect on growth. On the other hand, when used in combination either with ammonium sulphate or with a complete fertilizer a much greater growth was secured than where either of these was used without sulphur. Determination of the dry substance in the various plants as made by Gronover appeared to confirm these results. Likewise a bacteriological investigation by Hiltner indicates that sulphur has a favorable influence on the development of bacteria in soils.

Hotbeds, L. G. HERRON (*Oklahoma Sta. Circ.* 23 (1913), pp. 8, figs. 3).—This circular contains instructions for the construction, care, and management of hotbeds, including details relative to the cost of construction.

The chayote (*Sechium edule*), I. BALDRATI (*Agr. Colon. [Italy]*, 8 (1914), No. 1, pp. 38-55, figs. 2).—An account of the chayote with reference to its botany, varieties, culture, food value, and methods of preparing for the table. A bibliography is included.

Kale fertilizers, T. C. JOHNSON (*Virginia Truck Sta. Bul.* 9 (1913), pp. 175-203, figs. 11).—This bulletin gives the plan in detail of a combined fertilizer, soil management, and cropping system experiment with truck crops started by

the station in 1908 in cooperation with the Bureau of Plant Industry. Results are also presented in tabular form and discussed, showing the effects of the various treatments as measured by a crop of kale grown during the season of 1912-13. The results obtained from crops previously grown are to be published elsewhere.

Thus far no definite conclusions are drawn as to the best fertilizer formula for kale. The results indicate in general, however, that a complete fertilizer should be used and that the highest yields will be secured when the soil is kept in good tilth by supplementary manure and humus treatments, such as crimson clover and lime or stable manure and lime.

Study on the crossing of peppers (*Capsicum annuum*), S. IKENO (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 10 (1913), No. 1-2, pp. 99-114, figs. 4).—The author reports his observations on F₂ pepper crosses, with special reference to color of flower, inflorescence, fruit stem, color and length of fruit, and hairiness.

Crosses of violet and white petaled flowers segregated according to Mendel's law, violet being dominant. Violet and mosaic violet-white petal colors were always combined with dark violet and blackish leaf and stem colors and white petals with green leaves and stems. Umbelliferous inflorescence was recessive to nonumbelliferous in the hybrid *C. annuum* × *fasciculatum* and its reciprocal. Erect position of the fruit stem was dominant in the flowering stage while the pendant position dominated in the fruiting stage. In crosses of red and orange fruited forms red was always dominant. Both the length and hairy characters showed all gradations between the 2 parents, indicating that these characters had to do with more than one genetic factor, at least in the crosses studied.

A B C of fruit growing, S. H. DIXON (*Texas Dept. Agr. Bul.* 32 (1913), pp. 160, figs. 61).—This is a popular guide to the culture and care of various orchard and small fruits with special reference to Texas conditions. Lists are given of varieties adapted to various sections of Texas, together with varieties of fruits which have originated in Texas.

Varieties of fruit for Arkansas, H. E. TRUAX (*Arkansas Sta. Bul.* 116 (1914), pp. 577-590, figs. 3).—This bulletin contains a descriptive list of thoroughly tested varieties of orchard and small fruits for culture in Arkansas. In preparing the list considerable weight has been given to the experience of reliable fruit growers in each section of the State.

Viticulture in Hungary, F. DE LÓNYAY (*Internat. Inst. Agr. [Rome]*, Mo. *Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1142-1149).—A brief descriptive and statistical review of viticulture in Hungary, including measures which have been taken to promote the welfare of the industry.

Orange culture in Montevideo, A. ABELLA (*Min. Indus. [Uruguay] Insp. Nac. Ganaderia y Agr. Bol.* 7 (1913), pp. 48, figs. 19).—The author here describes the method of growing and handling oranges on a typical plantation in Montevideo and offers suggestions relative to the improvement of present practices.

Cocoa, its cultivation and preparation, W. H. JOHNSON (*London*, 1912, pp. IX+186, pls. 12).—In the present treatise the author discusses the historical development of the cacao industry; the botanical, climatic, and soil requirements of cacao trees; the establishment, culture, and care of cacao plantations; the results of manurial experiments in various countries; diseases and their control; harvesting and transporting; cacao fermentation and fermentation processes in various countries; washing and sun drying cacao; yield and expenditure; and the manufacture and uses of commercial cacao.

Researches into some statistics of Coffea, P. C. VAN DER WOLK (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 10 (1913), No. 1-2, pp. 136-150, figs. 4; 11 (1913), No. 1-2, pp. 118-127, figs. 5).—In these two articles the author reports a biometric study, conducted at the Buitenzorg Experimental Gardens, of fluctuating variability in leaf length and internodal length in coffee plants.

Sweet peas up-to-date, G. W. KERR (*Philadelphia, 1914, rev. ed., pp. 88, figs. 14*).—The author here presents descriptive lists of all known varieties of sweet peas, including novelties for 1914. Notes on the culture and training of sweet peas are also given. The descriptions are based upon observations made at the Fordhook Farms, Bucks County, Pa., trial grounds during the past 6 seasons, as well as previous experience in England.

New roses, ROSE G. KINGSLEY (*London and New York [1913], pp. 161-178*).—This pamphlet is offered as a supplement to the author's previous book on roses (*E. S. R.*, 21, p. 335), and contains descriptive lists of the more important roses which have appeared since 1908.

Insecticides and fungicides, E. P. FELT (*N. Y. State Mus. Handbook 18 (1913), pp. 24*).—This pamphlet contains directions for the preparation and use of the more important insecticides and fungicides, together with a bibliography of entomological publications issued by the New York State Museum.

Spraying calendar for 1914, J. G. HALL and M. A. YOTHERS (*Washington Sta. Popular Bul. 59 (1914), folio*).—Concise instructions are given for the treatment of the principal pests and diseases of orchard fruits, including directions for the preparation of spray mixtures.

The new local option orchard and small fruit inspection law (Arkansas Sta. Circ. 18 (1913), pp. 4).—This circular contains the text of an act of the general assembly of the State of Arkansas, approved April 2, 1913, to prevent the increase and scattering of insect pests and plant diseases injurious to horticultural plants and crops.

The act creates a state board of orchard inspection, composed of the director, entomologist, and plant pathologist of the station, and provides for inspection in any township where the majority of the electors voting approve the adoption of the act at a general election for state and county officers. Whenever three-fourths of the townships of any county shall have adopted the provisions of the act, they are to be extended to the entire county.

FORESTRY.

Shortleaf pine in Virginia.—The increase in its yield by thinning, W. W. ASHE (*Richmond, Va.: Dept. Agr. and Immigr., 1913, pp. 44, pls. 7*).—The author here presents the results of a survey of the second growth shortleaf pine in old fields in the middle portion of Virginia. The survey was conducted cooperatively by the Forest Service of the U. S. Department of Agriculture and the State of Virginia to ascertain the value of this shortleaf pine timber for lumber uses, to determine the effect of lumbering on the future yields of the stands and whether conservative methods of cutting could be employed profitably, to determine the yield of stands of different ages, to recommend methods of thinning and cutting to accelerate growth, and to devise methods of protection for young growth.

The subject matter is discussed under the following general headings: Distribution and importance, condition and position of old-field stands, management, thinnings, production of cordwood from thinned and unthinned stands, production of saw timber, value of trees and stands, waste in cutting small trees, lumbering and restocking, planting waste lands, and the protection of stands.

The investigation shows as a whole that shortleaf pine is already one of the chief sources of building material on the farms. If young stands are protected, full stocking secured, and the stands subsequently thinned, the yield of saw timber from a 40-year-old stand can be more than doubled and its value greatly increased, thereby furnishing a means of permanent income from the farm woodlots.

White pine under forest management, E. H. FROTHINGHAM (*U. S. Dept. Agr. Bul. 13* (1914), pp. 70, pls. 7).—This bulletin summarizes the most important facts relative to white pine with regard both to the original forest and to the second growth. Yield tables for second growth stands based on measurements made in southern New Hampshire by C. A. Lyford and L. Margolin are given, and from these data tables are derived showing the value of stumpage at prevailing prices and the profit or loss resulting from the management of second growth under favorable and unfavorable conditions. Methods are suggested for securing the successive crops and for increasing the quantity and quality of the yield. Chapters on Direct Seeding and Protection from an unpublished report on white pine by A. K. Chittenden and J. S. Ames are also given.

Owing to the success with which white pine lends itself to management, the relatively steady market, and the small amount of waste in lumbering, it is concluded that under widely varying conditions of quality and accessibility and with the prevailing tax rates, market value, and wages, the raising of white pine to ages of from 35 to 70 years is a profitable undertaking at 4, 5, 6, and sometimes 10 per cent compound interest.

Yellow poplar in Tennessee, W. W. ASHE (*Tenn. Geol. Survey Bul. 10-C, 1913, pp. 56, figs. 8*).—This embraces the results of a survey of second growth poplar stands in Tennessee, conducted cooperatively by the Forest Service of the U. S. Department of Agriculture and the State Geological Survey, with special reference to determining the rate of growth of the young timber, the possible profit in growing it, and the best methods of management for accelerating its growth and increasing its value. The principal phases discussed are commercial outlook, distribution, forest characteristics, silvical characteristics, growth, increasing the yield from timber land by management and better utilization, and the establishment of yellow poplar plantations, including cost estimates.

The investigation as a whole shows that not only is there an assured and remunerative market for the timber of small-sized trees but its rate of growth is so rapid that returns are obtained at an early period for a forest tree.

Notes on tapping experiment at Gunong Angsi, F. G. SPRING (*Agr. Bul. Fed. Malay States, 2* (1913), No. 5, pp. 119-123).—The second year's results from tapping experiments with Para trees at Gunong Angsi (E. S. R., 28, p. 239) show that tapping in adjacent quarters not only gives a higher yield than tapping in opposite quarters, but that it is a much more economical system to adopt. A 2-year bark renewal system is more expensive and less satisfactory in yield of rubber than a 4-year bark renewal system. Trees tapped in adjacent quarters showed a considerable increase in girth over trees tapped in opposite quarters. The yield of rubber and girth of trees growing at an elevation of 800 ft. were somewhat greater than for trees growing at an elevation of 1,000 ft. In this connection attention is called to the fact that the trees growing at the lower altitude are spaced 25 by 23 ft., as compared with 15 by 15 ft. for trees at the higher altitude.

The cultivation of the Tung tree (China wood oil) in the United States, D. FAIRCHILD (*Paint Manfrs. Assoc. U. S. Bul. 33, pp. 4-19, figs. 6*).—An account of the experiments of the Bureau of Plant Industry of the U. S. Department of

Agriculture in the introduction of the Chinese wood-oil tree (*Aleurites fordii*). A subsequent account of this work has been noted (E. S. R., 28, p. 843).

On some timbers which resist the attack of termites, R. KANEHIRA (*Indian Forester*, 40 (1914), No. 1, pp. 23-41).—The author here presents a list of construction timbers which have been found resistant to the attack of termites in various tropical countries, together with a list of seasoned and unseasoned Formosan timbers showing their relative immunity when inspected at intervals of 6 months and a year after burying. From the experiments thus far made it is concluded that the termite resistance of various timbers may be due to the presence in the wood of certain species of some substance with a strong smell or taste disagreeable to insects; to the presence of poisonous substances in certain species; and to the extreme hardness of the wood in others.

A bibliography of reference works is given.

The lumber industry (*Thirteenth Census U. S.*, 10 (1910), pp. 485-508, figs. 2).—This comprises both detailed and summarized statistical reports on the lumber industry of the United States, compiled from data secured in 1910 but relating to the year 1909. The data given include 4 classes of establishments, namely, logging camps and merchant sawmills, including planing mills where operated in connection with sawmills; independent planing mills; wooden packing-box factories; and custom sawmills. These establishments are considered with reference to number; persons engaged in the industry, either as proprietors or employees; primary horsepower; capital; wages; cost of materials; value of products; and value added by manufacture. Comparative data are also given for previous census periods.

The total number of establishments reporting was 44,804; the number of persons engaged in the industry, 797,825; the amount of capital invested, \$1,182,330,552; the value of products, \$1,160,644,628; and the value of products less cost of materials, \$652,425,475. The statistics relative to lumber, lath, and shingle production correspond to those previously issued (E. S. R., 25, p. 240).

Wood-using industries of Ohio, C. W. DUNNING (*Ohio Sta. Wood-Using Indus.*, 1912, pp. 133, figs. 30).—This report comprises the results of a survey of the wood-using industries of Ohio, conducted cooperatively by the Forest Service of the U. S. Department of Agriculture and the Ohio Station. The data given and discussed show the consumption and value of domestic and imported woods by species and by industries, including also the kinds of woods used by each industry, and the average cost per thousand feet. A list is also given showing the use of domestic and foreign woods in the manufacture of various articles, together with a directory of wood-using manufacturers.

In order to make the report more complete the statistics of the Bureau of the Census referring to Ohio have been compiled and are here given.

Wood-using industries of New York, J. T. HARRIS (*N. Y. State Col. Forestry, Syracuse Univ.*, Ser. XIV, No. 2 (1913), pp. 213, pls. 7).—This report comprises the results of a survey similar to the above of the wood-using industries of New York, conducted cooperatively by the Forest Service of the U. S. Department of Agriculture and the New York State College of Forestry.

Wood-using industries of South Carolina, S. L. WOLFE (*Columbia, S. C.: Dept. Agr., Com., and Indus.*, 1913, pp. 53, pls. 14).—This is an investigation similar to the above of the wood-using industries of South Carolina, conducted cooperatively by the Forest Service of the U. S. Department of Agriculture and the Department of Agriculture, Commerce, and Industries of the State.

DISEASES OF PLANTS.

The parasitology of agricultural plants, M. NEVEU-LEMAIRE (*Parasitologie des Plantes Agricoles. Paris*, 1913, pp. XII+720, figs. 430).—In this work the

author describes the parasites occurring on some of the principal field, forage, and garden crops, discussing them as far as possible in the systematic order of the parasites. The first part of the book is devoted to plant parasites, while the second treats of animal parasites. Following the description of each species, the pathogenic rôle is indicated. A list is given of the host plants, the different parasites being classified according to the part of the host plant attacked.

Report of committee on fungus diseases for 1911, F. D. HEALD (*Texas Dept. Agr. Bul.* 22 (1911), pp. 158-163).—The author lists as sufficiently abundant to attract very general attention the following diseases:

Powdery mildew of rose (*Sphaerotheca pannosa*), rose leaf blotch (*Actinonema rosæ*), apricot scab or freckle (*Cladosporium carpophilum*), bacterial blight of geraniums (species not yet determined), blossom-end blight of the watermelon (cause not definitely known), bacterial canker of plum (species not yet determined), and dieback or winterkilling of peach, plum, and apricot (*Valsa leucostoma*).

Remedial measures are suggested in connection with each disease.

Suppression of plant diseases—Ireland and international action (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 4, pp. 661-664).—The successful handling of the situation regarding international trade caused by the recent appearance of black scab of potatoes in Ireland is cited and discussed in its bearings upon a possible international arrangement in view of this and related dangers, with a brief account of measures taken or contemplated to that end.

The powdery mildews—Erysiphaceæ, G. M. REED (*Trans. Amer. Micros. Soc.*, 32 (1913), No. 4, pp. 219-258, pls. 4).—The author describes the general characteristics of the Erysiphaceæ, the group of fungi to which the powdery mildews belong, and gives accounts of the development of the perithecium, host distribution, biological specialization, economic importance, and pathological effects of the powdery mildews. The classification of the species is treated at length, keys for their identification being given. A host index and a bibliography of literature are included.

Ramularia, Mycosphærella, Nectria, and Calonectria, H. W. WOLLENWEBER (*Phytopathology*, 3 (1913), No. 4, pp. 197-242, pls. 3).—The results of a morphological and pathological study on the differentiation of species of fungi belonging to these groups are given.

So far as pure culture investigations are concerned, the author found that among the Ascomycetes septocylindrical conidia were wanting in *Fusarium* proper but occur in certain sections of *Nectria*, *Hypomyces*, *Mycosphærella*, etc. *Hypomyces* is said to divide itself readily into several sections, which are described. The genus *Ramularia* is said to embrace a number of wound parasites. *Septocylindrium* does not differ in any material way from *Ramularia* and they should be combined.

According to the author, *N. galligena*, the cause of canker of fruit and other deciduous trees in Europe, and *C. graminicola*, which produces the snowy mold of cereals, are present in the United States.

Notes on cultures of three species of Peridermium, G. G. HEDGCOCK and W. H. LONG (*Phytopathology*, 3 (1913), No. 4, pp. 250, 251).—Accounts are given of infection experiments with species of *Peridermium* in which the alternate hosts were determined. Sowings of æcidospores of *P. inconspicuum* on *Coreopsis verticillata* showed infection, and the name for the fungus, based upon this form, is given as *Coleosporium inconspicuum* n. comb. In addition *P. delicatulum* from *Pinus rigida* was found to grow on *Euthamia graminifolia*, and the name *C. delicatulum* n. comb. is given for the fungus. The connection

between *Peridermium stalactiforme* on *Pinus contorta* and *Castilleja linearis* is shown by successful cultures.

An undescribed species of *Peridermium* from Colorado, G. G. HEDGCOCK and W. H. LONG (*Phytopathology*, 3 (1913), No. 4, pp. 251, 252).—*P. betheli* n. sp. occurring on *Pinus contorta* is described.

Alfalfa leaf spot disease, T. G. B. OSBORN (*Jour. Dept. Agr. So. Aust.*, 17 (1913), No. 3, pp. 294–296, figs. 4).—This disease of *Medicago sativa*, caused by *Pseudopeziza medicaginis*, is said to have been noted on a farm of the department at Turretfield in December, 1912.

Frequent cutting and early removal of the hay is recommended so as not to leave many dead leaves. In case of severe infection, burning of the cut and dried hay (adding a layer of straw if necessary) is recommended. It is thought that this disease may be spread in soil used to convey nodule bacteria or else in the seed.

It is said not to be definitely known whether *P. trifolii* (which produces a very similar leaf spot disease of clover) is capable of infecting alfalfa.

A new fungus disease of clover, A. BONDARTSEV (*Zhur. Bol'ezni Rast.*, 7 (1913), No. 1–2; *abs. in Riv. Patol. Veg.*, 6 (1913), No. 6, p. 178).—The author describes a fungus said to be parasitic in clover blossoms in parts of Russia. The species has been named *Botrytis anthophila* n. sp.

Report of the botany division, H. W. BARRE (*South Carolina Sta. Rpt. 1913*, pp. 14–20).—In the cotton anthracnose investigations, it was found that the planting of seed from bolls obtained from stalks showing any disease whatever is an unsafe practice. Plants grown from seed taken from healthy stalks have been free from disease. Laboratory and field tests with diseased seed have shown that the centrifuge and germination tests are safe indicators of the presence of disease, but no basis has been formed for determining the amount of disease to be expected from a given sample of seed. The work in seed treatment for the control of the disease has been continued, and although treated with concentrated sulphuric acid until the lint was completely destroyed, a considerable amount of disease was developed from seed taken from diseased stalks but on bolls showing no definite signs of the disease. In the progress of this investigation different strains of the anthracnose fungus (*Glomerella gossypii*) have been secured, and it is thought that probably the variation in the amount of disease in the same varieties of cotton from year to year may be due to the virulence of the fungus. A survey of the State shows that the anthracnose is present in every county in the State.

The investigations begun on cotton shedding have been continued, and several new phases of the problem have been studied under controlled conditions. It has been found that the fertility of the soil is a decided factor in the amount of water required to produce a pound of seed cotton, the amount varying from 80 to 125 gal. of water for 1 lb. of seed cotton, and depending on soil fertility and other soil conditions. The second year's experiments in irrigation confirmed the conclusion of the previous year that soil moisture is an important factor in cotton shedding. Considerable data have been collected on the relation between leaf area, transpiration, shedding, and yield.

The cotton and cowpea wilt work, carried on in cooperation with the Bureau of Plant Industry of this Department, is briefly described, and notes are given on the work of the pathological inspection and plant disease survey.

Texas root rot of cotton, F. D. HEALD (*Texas Dept. Agr. Bul.* 22 (1911), pp. 303–308).—Besides a brief discussion of sore shin (*Rhizoctonia* spp.) and cotton wilt (*Fusarium vasinfectum*), more particular attention is given to Texas root rot of cotton (*Ozonium omnivorum*). This is said to attack also many wild and cultivated plants, cereals furnishing an exception. As a means

of combating this fungus, a three years' succession of wheat, corn, and sorghum is recommended. Aeration of the soil by deep fall plowing has also been found effective.

A new type of bacterial disease, E. F. SMITH (*Science, n. ser.*, 38 (1913), No. 991, p. 926).—A brief description is given of a disease of orchard grass formerly described by Ráthay (E. S. R., 11, p. 759). This disease is of bacterial origin and the growth first develops as a thick layer on the surface of the plant, later penetrating into the interior. It is proposed to call the organism, which has been isolated, *Aplanobacter ráthayi* n. sp.

Diseases affecting potatoes, M. T. COOK (*Ann. Rpt. N. J. Bd. Agr.*, 40 (1912), pp. 155-161).—Besides a brief discussion of the various potato diseases infesting or threatening this section, with known or suggested remedies, the author proposes the organization of a potato growers' association for the State with a view to protecting this crop from disease in New Jersey.

Report on the prevalence of potato blight in Ireland up to mid-July, 1913 (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 4, pp. 732-734).—It is stated that while potato blight was reported from different counties, the disease showed no tendency to spread rapidly. Outbreaks were confined chiefly to early varieties, owing probably to the backwardness of the crop, favorable weather, and more general spraying. Investigations are reported as still in progress regarding black stalk rot, stalk disease, and yellowing, which in recent years have caused considerable injury to the potato crop, especially in the west of Ireland.

Spraying tests against potato blight, G. QUINN (*Jour. Dept. Agr. So. Aust.*, 17 (1913), No. 3, pp. 301-306).—Giving results of several series of experiments, a number of which were contradictory and inconclusive, the author states that the history of the disease seems to indicate that in very dry climates it is problematical whether it pays in the long run of years to spray potatoes against Irish blight if the crops be grown during the summer months.

Further contribution to the study of Fusarium leaf roll of potato, W. HIMMELBAUR (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 42 (1913), No. 5, pp. 711-736, pl. 1, figs. 8).—Further study (E. S. R., 28, p. 848) is claimed to support the view that this disorder is due to a *Fusarium*. The varieties most resistant to the attack were those which most quickly formed cork on wounded surfaces. A temporary rolling of the leaves, it was found, may be produced by injury to the vascular bundles. Wounding the lower portion of the stem showed no considerable effect on the yield of tubers.

The pathological anatomy of potato scab, B. F. LUTMAN (*Phytopathology*, 3 (1913), No. 5, pp. 255-264, figs. 10).—Attention is called to the fact that most of the studies on the potato scab have been concerned with methods of prevention, and the author gives an account of his investigations on the pathology of the disease.

He finds that scabs may originate at any place on the potato, frequently occurring at the lenticels. The scab is due to the hypertrophy of the cells of the cork cambium. A surface view of the brown spots on the skin of scabby potatoes and very young scabs show the thread-like filaments of the fungus which apparently produces the disease. The carbon compounds stored in the diseased tissues consist of a large number of fat globules instead of the usual starch grains.

The efficiency of formaldehyde in the treatment of seed potatoes for Rhizoctonia, W. O. GLOYER (*New York State Sta. Bul.* 370 (1913), pp. 417-431, pl. 1).—The author investigated the relative efficiency of the standard scab treatments in the disinfection of seed potatoes affected with *Rhizoctonia*, for-

maldehyde gas, formaldehyde solution, and corrosive sublimate solution being compared.

It was found in laboratory experiments that neither formaldehyde gas nor solution can be depended upon to kill all the *Rhizoctonia sclerotia*. This seems to be due to the inability of the formaldehyde to penetrate to the center of the larger and more compact sclerotia. The standard corrosive sublimate treatment, on the contrary, was found thoroughly efficient, and even when used in a strength of 1:2,000 the corrosive sublimate solution killed all the *Rhizoctonia sclerotia*. The author concludes that when it is desired to treat seed potatoes for *Rhizoctonia* the corrosive sublimate should be used.

The injurious effect of formaldehyde gas on potato tubers, F. C. STEWART and W. O. GLOYER (*New York State Sta. Bul.* 369 (1913), pp. 385-416, pls. 2).—In 1912 the authors undertook the disinfection of a quantity of seed potatoes by the formalin-permanganate method, and as a result a great amount of injury was caused. Investigations were subsequently inaugurated to determine the cause of the injury, temperature, relative humidity, quantity of potatoes in proportion to space, and varietal differences being studied. It was found that the chief cause of the injury was the small quantity of potatoes per cubic foot of space in the fumigation chamber, although high relative humidity and the sprouted condition of the potatoes were important accessories.

Other experiments were carried on which have demonstrated the cause of the injury and how to avoid it. It was found that potatoes absorb a considerable quantity of the gas, resulting in two forms of injury, one called lenticel spotting and the other where the eyes are affected. In the experiments lenticel spotting occurred with all quantities of tubers used up to 12 lbs. per cubic foot, but no eye injury appeared when 5 lbs. or more per cubic foot were used. The effect of the lenticel spotting on germination and growth has not been definitely determined, but it is believed to be without material injury to the tubers for seed purposes.

In view of their experiments the authors recommend the use of gas treatment only where liquid treatments are impracticable, and they recommend as safe and efficient treatment for scab the use of 3 pints of formaldehyde and 23 oz. of permanganate of potash to 167 bu. of potatoes in 1,000 cu. ft. of space.

In the course of the investigations it was found that similar injury to that produced by formaldehyde gas was produced by fumes of ammonia, bromin, or ether, and that strong solutions of formaldehyde and corrosive sublimate had somewhat similar effects. In the use of formaldehyde solution the quantity of potatoes treated had no appreciable influence on the degree of injury, and it was found that the same solution may be used at least ten times without loss of strength.

Certain varieties of apples are also reported as being injured by formaldehyde gas.

Some faults in formaldehyde disinfection of potatoes, F. H. HALL (*New York State Sta. Buls.* 369 and 370, popular ed., pp. 10).—This is a popular edition of the above bulletins.

Diseases of rice, E. J. BUTLER (*Agr. Research Inst. Pusa Bul.* 34 (1913), pp. 37, pls. 3, figs. 3).—A further account (*E. S. R.*, 28, p. 151) is given of studies by the author on a disease of rice attributed to a nematode claimed to be new and named *Tylenchus angustus*, which is discussed at some length; also some fungus diseases of rice, including bunt ascribed to *Tilletia horrida*, false smut to *Ustilaginoides virens*, and sterility to *Sclerotium oryzae*.

The important cane fungi in Santo Domingo, J. R. JOHNSTON (*Rpt. Bd. Comrs. Agr. P. R.*, 2 (1912-13), pp. 29-31).—The author reports having found the following important cane diseases in Santo Domingo; Root disease, ascribed

to *Marasmius sacchari*, said to be often associated with some other fungi; rind disease, due to *Melanconium sacchari*; red rot of the stem, due to *Colletotrichum falcatum*; pineapple disease, due to *Thielaviopsis paradoxa*; and red spot of the leaf sheath, due to *Cercospora vaginæ*. Some others found caused serious injury only under exceptional conditions.

On the identity of *Bacillus nicotianæ* with *B. solanacearum*, J. A. HONING (*Rec. Trav. Bot. Néerland.*, 10 (1913), No. 2, pp. 85-136, figs. 3).—The author, giving an account of studies on the morphology and parasitic activity of the organism associated with "gummosis," black shank, or bacterial tobacco wilt, states that *B. nicotianæ*, described by Uyeda (E. S. R., 18, p. 151), is identical with that previously described as *B. solanacearum* by Smith (E. S. R., 8, p. 895).

It is stated that this organism may sometimes be observed to lose its virulence, first for *Capsicum annuum*, later for *Nicotiana tabacum*, and finally for *Solanum melongena* and *S. lycopersicum*. This circumstance probably tends to explain the disagreement noted in the reports above mentioned.

Weather and stalk disease of wheat, E. VOGES (*Deut. Landw. Presse*, 40 (1913), No. 83, pp. 993, 994, figs. 3).—The author reports finding on wheat affected with foot rot or stalk disease besides *Ophiobolus herpotrichus* a number of other fungi named, and he holds that in this disease, as probably in some others, different causes may produce very similar results.

A discussion of the weather in connection with the progress of certain crop diseases during the past three years concludes with the statement that weather exerts both direct and indirect influence upon the relations between host and parasite.

Studies on frost injury to fruit trees, P. SORAUER (*Naturwissenschaften*, 1 (1913), Nos. 44, pp. 1055-1058, figs. 4; 45, pp. 1094-1097, fig. 1).—It is stated that even moderate cold is capable of producing wounds in fruit trees in regions of loose cortical tissue, particularly in case of certain varieties named. The attacks of fungi are favored by the lesions produced. Both these features are accentuated in case of quick-growing trees under the influence of nitrogenous fertilizers with free irrigation.

Winter injury in orchards, F. M. CLEMENT (*Ann. Rpt. Quebec Soc. Protec. Plants [etc.]*, 5 (1912-13), pp. 24-26).—The observed effects of expansion and contraction in splitting the bark of fruit trees are discussed in connection with their relation to attack from organisms causing disease. These injuries (believed to favor development of black rot canker and crown rot in apple trees) are said to be prevented or greatly minimized by protecting the trees from strong wind and direct sunshine.

The black spot of the apple and pear, H. M. NICHOLLS (*Agr. Gaz. Tasmania*, 21 (1913), No. 10, pp. 387-401, figs. 6).—Besides a brief illustrated description and biological history of *Venturia inæqualis* and *V. pyrina*, causing black spot respectively of apple and pear, some remedial measures as tried in Tasmania are recommended. These are essentially the same for both fungi and consist in early plowing in of the fallen leaves, harrowing down the surface soon after, leaving it undisturbed until after November 15, and spraying the trees early in October with Bordeaux or Burgundy mixture, or with lime sulphur adding 1 lb. of wheat flour to each gallon of the solution to promote spreading and adhesion. For the control of the disease in packed fruit, good ventilation is said to be usually effective.

Quince blotch and apple fruit spot, C. BROOKS (*Phytopathology*, 3 (1913), No. 4, pp. 249, 250).—The author notes the occurrence on Chinese quince of the fungus *Phoma pomi*, and calls attention to the identity of this species with that from the apple and other species of quinces.

Comparative studies of certain disease producing species of *Fusarium*, C. E. LEWIS (*Maine Sta. Bul.* 219 (1913), pp. 203-258, pls. 15).—In a study of apple decays the author found in 1908 two species of *Fusarium* in decaying fruits. Since that time a considerable number of apples have been found in which a *Fusarium* was causing decay. This led to a study of various species of *Fusarium*, forms from 24 sources being investigated at considerable length, and an equal number of additional forms being studied but not reported upon in detail. The growth and cultural characters of the organisms are described and accounts given of the results of inoculation experiments to test the pathogenicity of the various strains on different host plants.

The two species mentioned above as occurring on the apple were found capable of causing the decay. One is considered very similar to, if not identical with, *F. putrefaciens*, a cause of apple decay in Europe. The other species is said to resemble very closely the fungus which causes a rot of carnations, described by Stewart as *Sporotrichum pow* (E. S. R., 20, p. 647), differing, however, from that species by having a larger proportion of septate spores in the apple fungus.

In an appendix to the bulletin, W. J. MORSE gives a list of species studied as determined by Wollenweber, and also a host index that shows a wide range of hosts for the different species. With the possible exception of *F. conglutinans*, all of the strains produced some decay on some varieties of apples.

Is apple scab on young shoots a source of spring infection? W. J. MORSE and W. H. DARROW (*Phytopathology*, 3 (1913), No. 5, pp. 265-269).—There is said to be little unanimity of opinion among investigators as to the part played by young branches and water shoots in the spring occurrence of apple scab. The authors have made a study of this matter, examining a large number of trees, and while they do not wish to be understood as denying that the ascospores formed on the leaves of the previous year are the source of a great proportion of the spring infection of apple scab, it is thought that under certain conditions and with certain varieties of apple trees, diseased twigs and water sprouts are an important factor in the propagation and spread of the disease at the beginning of the following year. Attention is called to the fact that the application of some strong fungicide before the opening of the leaf buds would doubtless greatly reduce infection from this source.

Apple rust found on fruit, A. DE JACZEWSKI (*Bul. Trimest. Soc. Mycol. France*, 29 (1913), No. 1, pp. 165-169, fig. 1; *abs. in Bot. Centbl.*, 123 (1913), No. 5, p. 115).—The author reports finding in September, 1912, on the surface of diseased apples, æcidia characteristic of *Ræstelia*, heretofore supposed to be confined to leaves and branches.

Biologic forms of black knot, E. M. GILBERT (*Phytopathology*, 3 (1913), No. 4, pp. 246, 247).—The author notes the common occurrence of black knot (*Plowrightia morbosa*) on some species of *Prunus*, while it is almost entirely absent from others.

Inoculation experiments with black knots from cultivated varieties of plums were made, using wild plum, choke cherry, and pin cherry. The results of the experiments show that in no instance was there the formation of any structure that could be compared to the typical black knot. It would appear that the black knot of the wild plum and the choke cherry are biological forms and that this may also be true of the form found upon cultivated varieties.

Vine chlorosis and its treatment, L. RAVAZ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 47, pp. 641-652).—Discussing the results of experiments by Mazé with maize (E. S. R., 28, p. 429), and those of the same author in connection with Ruot and Lemoigne (E. S. R., 29, p. 826) on legumes, in which the chlorosis following use of calcium carbonate was relieved on addi-

tion of iron compounds, the author suggests the utilization in connection with grape chlorosis of certain iron bearing soils widely distributed in France.

On the proportion of iron sulphate used against white rot of grapevines, M. BLUNNO (*Rpt. Austral. Assoc. Adv. Sci.*, 13 (1911), pp. 562-566).—The author reports his experience with white rot of the root system of grapevines, associated with *Dematophora necatrix*. Carbon bisulphid applied at the rate of 1 oz. per vine, divided into 5 partial injections, 6 or 8 in. from the stem, was effective during the first stage of the infection, but could not destroy the foci of infection represented by roots of once existing trees, and repeated and stronger doses endangered the vines. Ferrous sulphate applied once annually for 3 successive years at the rate of 8, 16, and 16 oz., respectively, to each vine was sufficient to restore all but 2 vines, in which the chlorosis yielded to a further and slightly modified treatment. This salt is thought to act not only as a fungicide, but as a vigorous stimulant to growth.

The present status of the defensive treatment for cacao canker in Samoa, K. FRIEDERICHs (*Tropenpflanzer*, 17 (1913), No. 10, pp. 571-578).—The author claims that Bordeaux mixture applied carefully and thoroughly in August, October, and December is safely protective against cacao canker ascribed to *Phytophthora faberi*, if in connection therewith care is taken to destroy all parts of badly infected trees and certain insects mentioned.

Gummosis in roots and pods of *Acacia*, L. LUTZ (*Bul. Soc. Bot. France*, 60 (1913), No. 5, pp. 322-324).—Pursuant to a previous report (*E. S. R.*, 7, p. 468), the author states that the succession of phenomena characteristic of the progress of gummosis in *Acacia* is the same in the roots as in the trunk, but in general of later occurrence in the former, as marked by clogging or obliteration of the vessels. Although lesions appeared on the pods, the seeds were not affected.

Twig canker on black birch, C. HARTLEY (*Phytopathology*, 3 (1913), No. 4, pp. 248, 249).—During the winter of 1910 a twig canker was reported as doing serious damage to *Betula lenta* in the New York Zoological Park. The twigs developed considerable swellings and the part beyond the swelling died. An examination of affected material showed the presence of *Sphaeropsis*, *Cytospora*, and *Myxosporium*, and inoculation experiments were carried on with the different fungi.

The results showed some infection, but further inoculations on young rooted trees gave negative results. This is believed to indicate that the *Sphaeropsis*, which seemed to be the most common species, is parasitic only under certain conditions, and that it is improbable that these fungi were concerned in causing the swollen cankers characteristic of the disease.

The chestnut bark disease, H. METCALF (*Jour. Heredity*, 5 (1914), No. 1, pp. 8-18, figs. 8).—The author gives an account of the chestnut bark disease, due to *Endothia parasitica*, suggesting its possible introduction from the Orient, and describes its distribution, manner of infection, symptoms, etc. For the control of the disease it is thought that probably the breeding of immune or highly resistant varieties will be necessary.

The chestnut bark disease on chestnut fruits, J. F. COLLINS (*Science*, n. ser., 38 (1913), No. 989, pp. 857, 858).—The author reports the observation on nuts and burs of the chestnut of reddish-brown pustules resembling those of *Endothia parasitica*. Portions of the diseased fruits were successfully inoculated into the bark of chestnut trees, producing typical infection.

The results of the inoculations indicate that the disease was present on or in the nuts and burs collected, and while diseased nuts are not likely to often reach the market, yet the possibility of the dissemination of the disease in this manner should not be overlooked.

Chestnut blight resistance, R. T. MORRIS (*Jour. Heredity*, 5 (1914), No. 1, pp. 26-29, figs. 2).—The author reports that in 1905 in a chestnut forest in Connecticut there were about 5,000 old American chestnut trees, a few chinquapins (*Castanea pumila*), and two saplings of *C. mollissima*, the Chinese chestnut. When it became evident that the chestnut bark disease was threatening the American chestnut trees an attempt was made to find blight resistant individuals, and plantings were made of 26 different kinds. These included the American species as well as a considerable number of others introduced from Europe and Asia. There were also a number of grafted varieties of different sorts.

In 1913 every one of the old American chestnut trees had become blighted and had been removed, and the younger trees and stump shoots are said to be practically all dead or dying with the blight. The various grafted varieties of European and Asiatic chestnuts showed different degrees of resistance to blight. This was also true of the seedlings of European and Asiatic varieties. None of them appeared to be quite as susceptible to the disease as the American chestnut, but most were affected and ultimately died. The Korean chestnuts and chestnuts from the Aomori region in Japan resisted the blight almost completely until they were about six years old. Since that time they have shown a tendency to attack, but resist the fungus somewhat better than the American chestnut. The Korean and Japanese chestnuts when grafted on American chestnut sprouts all blighted in their second or third year, seeming to indicate that the sap from the American chestnut had made them susceptible to the fungus. A hybrid between the American sweet chestnut and the chinquapin blighted when about 8 years old. None of the American species of the chinquapin, varying from 5 to 13 years, has blighted, with the exception of 2 limbs, which were injured by the falling of another tree upon them. None of the specimens of *C. alnifolia* nor *C. mollissima* has thus far shown any indication of blight.

A number of hybrids between the different species have been made and are being tested for possible resistance. While making these hybrids the author discovered that parthenogenesis occurs among the Castaneas, and incidentally it was found that the same takes place in a number of species of walnut and hickory.

Injury by oak mildew, NIKODEM (*Centbl. Gesam. Forstw.*, 39 (1913), No. 10, pp. 438-440).—A brief account is given of the progress of oak mildew in Croatia, which increased from 1907 to 1911, when it became much less general. A sudden renewal of activity in 1912 and since has been noted in connection with the presence and increase of a leaf wasp (*Emphytus filiformis*), which is discussed in this connection.

Pustule formation on Hevea brasiliensis, J. KUIJPER (*Rec. Trav. Bot. Néerland.*, 10 (1913), No. 2, pp. 137-146, pl. 1, figs. 7).—The author describes an abnormal condition of the cortex, observed on the lower portions of two young rubber trees, and thought to be related to that previously mentioned by Petch (E. S. R., 28, p. 246). Almost no latex is obtained from the roughened portions. The pustules are said to be independent of subcortical buds or injuries so far as known, and to show no connection with the deeper portions of the wood.

Bark rusts of Juniperus virginiana, C. HARTLEY (*Phytopathology*, 3 (1913), No. 4, p. 249).—According to the author, the bark rusts of cedar in the vicinity of Washington, D. C., are mostly due to *Gymnosporangium clavipes*, *G. nidus avis*, and *G. effusum*.

An epidemic of needle diseases in Idaho and western Montana, J. R. WEIB (*Phytopathology*, 3 (1913), No. 4, pp. 252, 253).—The author describes *Lopho-*

dermum pinastri, which is said to be becoming very destructive to white pines and other species in the western National Forests, and also a needle cast of larch which is assuming epidemic form in the Priest River Valley.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Experiments on the destruction of voles (*Bul. Mens. Off. Renscig. Agr. [Paris]*, 12 (1913), No. 4, pp. 399-401; *abs. in Jour. Bd. Agr. [London]*, 29 (1913), No. 7, p. 621).—The damage caused by voles in the eastern districts of France in 1912 led to an appropriation of 250,000 francs for use in combating them. Since the use of Danysz virus was not attended with very satisfactory results experiments were made with the commercial virus, known as "Ratin," on 24 plats covering a total area of 2.3 acres, distributed over a badly infested area of 30,000 acres.

On these plats 321 dead and 178 living voles were found, or a mortality of about 70 per cent. Taking into consideration the rate of reproduction of the voles it is estimated that a mortality of 90 per cent must be attained before the treatment can be considered satisfactory, and this result was obtained on but 4 plats. The virus was most effective on pasture and old stubble. It is concluded that while Ratin may be classed among the preparations useful in the extermination of voles, its general employment can not be recommended. The experiments confirmed previous experience in that treatment on a large scale led to the emigration of the voles.

The relative lengths of the large and small intestines in rodents, T. D. A. COCKERELL, L. I. MILLER, and M. PRINTZ (*Proc. Biol. Soc. Wash.*, 26 (1913), pp. 205-207).—This paper reports the results of an anatomical study of six species of rodents.

Five important wild duck foods, W. L. MCATEE (*U. S. Dept. Agr. Bul.* 58 (1914), pp. 19, figs. 16).—Supplementing information relating to wild rice, wild celery, and pondweeds, previously noted (*E. S. R.*, 25, p. 757), studies are reported on 5 other important plant foods of wild ducks.

The tubers of the Delta duck potato (*Sagittaria platyphylla*), known to the hunters of the Delta and other parts of Louisiana as wild potato or wild onion, were found to furnish 70 per cent of the food of canvasbacks collected and more than 65 per cent of the food of mallards, and the pintail was also found to feed upon them. This plant is thought to be hardy anywhere in the southern half of the United States, and may be proved to be so farther north. The second duck food considered is the wapato, represented by the 2 species, *S. latifolia* and *S. arifolia*. The former species is found from the Atlantic to the Pacific coast, its range covering practically the whole United States, while the latter is confined to States from Michigan and Kansas westward. In the course of the studies, the Biological Survey has found various parts of *Sagittaria* plants in stomachs of the following species of waterfowl: Mallard, widigeon, green-winged teal, blue-winged teal, spoonbill, pintail, canvasback, little bluebill, ruddy duck, Canada goose, and whooping swan. The remaining 3 duck foods discussed are the chufa (*Cyperus esculentus*), wild millet (*Echinochloa crus-galli*), and banana water lily (*Nymphaea mexicana*). In the discussion of the plants directions are given for their propagation.

Report of entomologist, A. F. CONRADI (*South Carolina Sta. Rpt.* 1913, pp. 20-24).—This report consists mainly of a brief discussion of the progress of two Adams Fund projects, the first, that of the relation of temperature and moisture to insect activity; and the second, that of the slender wireworm of cotton and corn.

In studying the relation of moisture to the hibernation of several species, exact weights were taken daily, commencing at a date previous to hibernation and continuing through the entering and leaving of hibernation. It was found that the weight at hibernation varied from 28 per cent in the squash bug to 32 per cent in the potato beetle, lower than constant weight during activity prior to and after hibernation. The invariable habit of these insects of avoiding places containing a high percentage of moisture leads the author to conclude that their reduction in weight is due to the elimination of moisture preparatory to hibernation. These species are less resistant to low temperature when in a moist environment, no individuals surviving 45 to 52° F., when exposed to ice in an ice box, owing to the saturation of the air, and the same was true in the case of eggs of the squash bug.

Further studies of *Hortistonotus uhleri* show that the larvæ are injurious only on barren upland soils; the larvæ avoid moisture and occur mainly on porous, lean, sandy, upland soils that will not saturate at any time.

Studies were also made of the cotton root louse and *Lasius niger americana*, its principal attendant.

The studies of wireworms have shown *H. uhleri*, *Monocrepidius vespertinus* and *M. lividus*, to be the species concerned, the first mentioned being the cause of nearly all the trouble. The investigations show *H. uhleri* to have an annual life cycle, the adults appearing in June and laying eggs during June, July, and August. It was found that the full-grown insects avoids packed or undisturbed soil in depositing its eggs.

Report on the prevalence of some pests and diseases in the West Indies during 1912, H. A. BALLOU (*West Indian Bul.*, 13 (1913), No. 4, pp. 333-347).—This third report (*E. S. R.*, 28, p. 248) treats briefly of the more important insect pests and plant diseases occurring in the West Indies in 1912.

Entomological pests and problems of southern Nigeria, A. D. PEACOCK (*Bul. Ent. Research*, 4 (1913), No. 3, pp. 191-220, pls. 6, figs. 2).—This relates to insects affecting cotton, cacao, maize, yams, rubber, mahogany, Arabian coffee, etc.

Some American insects and arachnids concerned in the transmission of disease, A. W. MORRILL (*Separate from Ariz. Med. Jour.*, 1914, Jan., pp. 12, figs. 8).—A paper presented before the Arizona Medical Association in May, 1913.

The Philippine locust (*Pachytylus migratoroides*); natural influences affecting its propagation and distribution, D. B. MACKIE (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 11, pp. 538-547, pls. 2).—The natural influences affecting this locust in the Philippines are dealt with under the headings of climate, food supply, and natural enemies, including predators, parasites, and diseases.

The parasitic enemies of the locust include three dipterans and two nematodes, the latter belonging to the genera *Gordius* and *Mermis*. Though reports have been received that whole swarms of locusts have been destroyed by these nematodes in Negros, reliable evidence is said to be lacking. The author's examinations have failed to show more than 7 per cent of the locusts to be parasitized by nematodes. Experimental work with *Cocobacillus acridiorum* obtained from Argentina has given negative results.

On the use of poison in the control of locusts in the Anglo-Egyptian Sudan, H. H. KING (*Cairo Sci. Jour.*, 7 (1913), No. 86, pp. 251-254).—The author briefly reviews the methods of controlling locusts which have been adopted in the Anglo-Egyptian Sudan in the past. He concludes that with ordinary care locusts can be controlled in the Sudan by the use of arsenite of soda and treacle, as has been done in other countries.

The biology of *Cimex boueti*, C. JOYEUX (*Arch. Par.*, 16 (1913), No. 1, pp. 140-146, figs. 8).—This hemipteran is said to occur commonly at various points in the Sudan.

The chinch bug (*Blissus leucopterus*), T. J. HEADLEE and J. W. MCCOLLOCH (*Kansas Sta. Bul.* 191 (1913), pp. 287-353, figs. 19).—This summarized account of the chinch bug is based upon a review of the literature and investigations conducted in Kansas. The subject is taken up under the headings of habits and life history, injury, natural checks, and measures of control.

"The chinch bug winters in bunch grass (*Andropogon scoparius*), big bluestem (*A. furcatus*) false redtop (*Triplasis purpurea*), and various other shelters. With the coming of spring the bugs leave their winter quarters and locate in wheat and other small grains. Here young are produced that reach maturity shortly after harvest time. With the failure of food in the small grain field these bugs migrate, usually on foot, into adjacent fields of corn and sorghum. Here young are produced that reach maturity by fall and establish winter quarters in the grasses. The chinch bug, both as young and as adult, damages its food plants by piercing the rind, sucking the sap, and killing the tissue about the wound. The chinch bug damages Kansas crops many millions of dollars in a single year, and many greatly reduce the wheat and absolutely destroy the corn and sorghums of the individual farmer. The chinch bug thrives in dry seasons and dies in wet ones. Wet weather destroys it directly and indirectly—directly by burying the young and the eggs; indirectly by weakening the bug and rendering it more susceptible of disease, and by encouraging the growth of its terrible fungus parasite (*Sporotrichum globuliferum*).

"The chinch bug has no efficient natural enemies other than certain parasitic fungi, the most active of which is *S. globuliferum*. The parasitic fungi are well distributed throughout that part of the United States subject to chinch bug outbreaks, and cause great epidemics when temperature and moisture become favorable. An average mean temperature of 75° F. and a moisture close to saturation are most favorable to the activity of *S. globuliferum*.

"All the really careful work thus far done on the problem agrees with our own results in showing that it is not possible by artificial distribution of the fungus materially to hasten the progress of the chinch bug disease caused by *S. globuliferum*. The advocacy of the control of the chinch bug by artificial distribution of the fungus has already cost Kansas many millions of dollars in staple crops through engendering the neglect of really efficient measures, and further advocacy of it is opposed to the best interests of Kansas agriculture. All the most careful tests at this station and elsewhere show that twice during the year the chinch bug may be destroyed—while passing from wheat and other small grains into adjacent fields of corn and sorghum, and when just firmly established in winter quarters. Destruction of chinch bugs in winter quarters by use of fire has proven, in our experience, the cheapest and most practicable method of solving the problem."

Burn the chinch bug in winter quarters, G. A. DEAN and J. W. MCCOLLOCH (*Kansas Sta. Circ.* 32, pp. 7, figs. 4).—This circular, emphasizing the importance of destroying the chinch bug in its winter quarters, is based upon the investigations reported in the bulletin noted above.

The grape leafhopper in the Lake Erie Valley, F. JOHNSON (*U. S. Dept. Agr. Bul.* 19 (1914), pp. 47, pls. 3, figs. 13).—This report is based upon studies of *Typhlocyba comae* conducted at North East, Pa., commenced in 1910, and includes frequent references to the literature. Reports of field experiments by the author have been previously noted (*E. S. R.*, 27, p. 758), as have studies by Hartzell of the New York State Station (*E. S. R.*, 27, p. 157).

The report contains a record of life history studies, together with a short historical account of the part this insect has played as an enemy of the grape-vine in other grape-producing sections of the United States and Canada. A detailed account is given of its habits and destructiveness, the kinds of remedies that have been devised for its control, and the nature of the spray equipment and spray material which, in recent experiments, have proved most effective in holding the pest in check.

The life history studies reported show that there is only one full brood of nymphs a year in the region of the Great Lakes. Field experiments prove conclusively that this pest can be controlled by spraying against the nymphs with tobacco extract solution.

"In the vineyards of Ohio, west of Cleveland, and in the vineyards of Michigan another species of grape leafhopper, *T. tricineta*, is the predominant and destructive species. The life history and habits of this species, however, are so nearly identical with those of *T. comes* that the remedial treatment recommended for the latter can also be used with success against the former, namely, the application of the tobacco-extract spray to the nymphs at the time they appear in maximum numbers upon the underside of the grape leaves, which for these States is during the last few days in June or very early in July."

A 4-page bibliography of the more important literature is appended.

Woolly aphid of the apple (*Schizoneura lanigera*), EDITH M. PATCH (*Maine Sta. Bul.* 217 (1913), pp. 173-188, pls. 6).—A further report of studies of this pest (*E. S. R.*, 28, p. 251), based upon observations made in 1913.

While the author has not as yet observed the return of the fall migrants to the elm under outdoor conditions, she has repeatedly during 2 years observed the spring migration from elm to apple and mountain ash and the subsequent development of the summer colonies so that there is no doubt that the species returns to the elm for the deposition of the winter eggs.

"On the elm the stem mother, which hatches from the overwintering eggs sheltered probably in rough crevices of the bark, appears early in the spring and may be found in Maine before the middle of May stationed on the partly opened leaf buds. The beak punctures on the rapidly expanding new leaves cause an unevenness of growth which forms a protection for the aphid. By the last of May the earliest of these wingless stem mothers are mature and found in the deformed elm leaves producing the next generation. . . . These nymphs, like the stem mother, are a wingless form and they become fully developed about June 10. . . . Their progeny are the third generation and attain wings. These winged aphids are known as the spring migrants. It takes 3 weeks or slightly more or less, beginning about June 20 for all the individuals of this third generation to get their growth, so that the migration covers a considerable period. . . . During this time these winged aphids may be found alighting on the leaves of apple, mountain ash, and hawthorn. They creep to the underside of the leaf and remain there while they give birth to their progeny (i. e., the fourth generation). These young, before they feed at all, crawl to the stem of the water shoots, or to some tender place on the bark, often near a pruning wound, and there start the colony on the summer host plant."

"There are apparently three summer generations of progeny of the elm leaf migrants upon the apple in Maine, two apterous generations followed by a generation part of which, the fall migrants, become winged and leave the apple, and part develop into apterous forms and, remaining on the apple, give birth to nymphs which while still young seek protection at the base of the tree for the winter and are known as the hibernating nymphs. It is the function of

the migrants to seek the winter host and there give birth to the true sexes. These are the tiny yellowish brown egg-laying females and the still smaller pale yellow males. Both sexes are wingless and with rudimentary mouth parts which are apparently functionless. . . . Such a cycle with the annual migration to and from the apple with the elm serving as host for the first three spring generations is undoubtedly typical for *lanigera*. The hibernating nymphs which remain protected about the crown of the apple over winter and ascend to tender places on the bark before feeding in the spring give what looks like a 'closed cycle' of apterous viviparous females persisting on the apple. . . .

"The case of the woolly aphid of the apple is still further complicated by the root colonies which although hidden in their operations really are often much more pernicious than the colonies on trunk and branches. These root colonies ordinarily remain underground all the year round, apparently until the roots become too badly demolished for feeding purposes."

The economic status of this species and preventive and remedial measures are discussed and structure and habitat keys given.

Pseudococcus filamentosus in Dar es Salaam, KRÄNZLIN (*Pflanzer*, 9 (1913), No. 10, pp. 493-507, pls. 6).—This mealy bug, also referred to as *Dactylopius perniciosus* (E. S. R., 24, p. 355), is the source of considerable injury in Dar es Salaam, German East Africa, to the valuable shade tree *Pongamia glabra*, lebbek trees (*Albizzia lebbek*), cotton, etc.

A new Eriococcus, E. O. ESSIG (*Jour. Ent. and Zool.*, 5 (1913), No. 4, pp. 179-181, figs. 2).—A species collected at Nacon Chico, Sonora, Mexico, on a species of *Cinchona* is described as *Eriococcus cockerelli*.

Pernicious scale.—The present position, C. P. LOUNSBURY (*Agr. Jour. Union So. Africa*, 6 (1913), No. 4, pp. 662-670).—A somewhat detailed account is given of the present distribution of the San José scale in Transvaal, Orange Free State, and Natal.

Contribution to the study of sericulture in Indo-China, BUI-QUANG-CHIÊU (*Bul. Écon Indochine*, n. ser., 16 (1913), Nos. 101, pp. 164-178; 102, pp. 376-401).—This paper deals with the history of sericulture, geographical distribution of the industry, races of silkworms, manner of rearing, diseases, the silk industry, and the mulberry in Indo-China.

Recent studies of the corpuscles found in pebrine of the silkworm, G. MARI (*Bol. Quind. Soc. Agr. Ital.*, 18 (1913), No. 3, pp. 86-92, fig. 1).—A review of recent work relating to *Nosema bombycis*.

The gipsy moth and the brown-tail moth, with suggestions for their control, A. F. BURGESS (*U. S. Dept. Agr. Farmers' Bul.* 564 (1914), pp. 24, figs. 10).—Brief popular accounts of these two pests, including their natural enemies, are followed by more detailed accounts of the approved methods of combating them.

Codling moth studies in 1911.—The driving spray under excessively wormy conditions, E. D. and W. M. BALL (*Utah Sta. Bul.* 129 (1913), pp. 265-300, figs. 2).—The authors' summary and conclusions drawn from the studies here reported are as follows:

"Western orchards, if unsprayed, would average from two to four or more worms per apple except in years of exceptionally heavy crops; therefore, methods and poisons must be able to meet successfully these conditions. The great majority of the first brood worms and over one-half of the second brood ones enter the calyx cups, therefore the most efficient spray will be the one that destroys the greatest percentage of these worms. The second brood of worms in Utah is ten or more times as large as the first; therefore, each first brood worm killed has saved ten worms in the second brood.

"The killing efficiency of a given method or of a given poison can, therefore, be very accurately measured by the calyx efficiency in the first brood. The killing 'efficiency' of a given spray is a much better measure of its value than the percentage of wormy apples in the orchard. The efficiency of a given spray on the first brood can be accurately measured without regard to the number of worms in an orchard or the method of checking, provided there are no more worms than apples.

"The first calyx spray (first spray) is by far the most valuable single spray that can be applied, killing 98 per cent of all worms entering the calyx during the year, and over 99 per cent of those in the first brood. This spray alone will not control seriously infested orchards, but must be combined with other sprays and banding.

"The standard poisons at the usual strengths (lead arsenate 5 lbs.) are not any stronger than are necessary to do efficient work. They cost less than one-half cent per box of apples. It is false economy to cut down the strength of the poisons."

Tests of the relative efficiency of the various sprays showed under extremely wormy conditions an efficiency with 5 lbs. lead arsenate of 100 per cent at the calyx and a total of 90 per cent for the first brood, and of 98 per cent at the calyx for the second brood. The corresponding efficiencies with 2½ lbs. arsenate of lead were 98, 80, and 80 per cent; with 5 lbs. of a proposed new proprietary compound 74, 45, and 46 per cent, and with 2½ lbs. of this compound 53, 74, and 17 per cent.

On the comparative effects of arsenic and lead in compounds employed in combating the *Cochylis*, L. MOREAU and E. VINET (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 11, pp. 906-908; *Rev. Vit.*, 39 (1913), No. 1007, pp. 489, 490; *abs. in Internat. Inst. Agr. [Rome]*, Mo. *Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 6, p. 967).—Repeated observations by the authors and others^a of the fact that *Cochylis* larvæ which escape destruction from arsenate of lead are small, weakly, yellow, and capable of effecting very little injury, while in neighboring plats treated with other insecticides the surviving larvæ are at the same time normal, well-developed, and as strong as control specimens, led to the investigations here reported. Applications of arsenate of zinc, arsenate of lime, lead acetate, and lead carbonate, as well as arsenate of lead, were made at the time of emergence of the first larvæ and again 8 or 10 days later.

By weighing the larvæ from the sprayed plats it was found that the effect was largely due to arsenic. The mortality was larger where arsenate of lead was employed than with the other arsenical sprays.

Wine traps for the *Cochylis* moths, L. MOREAU and E. VINET (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 23, pp. 1158-1160).—The authors conclude that traps of wine are only of value as a supplement to other measures.

The gray larch roller in the Upper Engadine (*Schweiz. Ztschr. Forstw.*, 64 (1913), No. 2, pp. 48-53).—This paper relates to *Steganoptycha pinicolana*.

A galleriine feeding in cacao pods, H. G. DYAR (*Insecutor Inscitiae Menstruus*, 1 (1913), No. 5, p. 59).—*Tineopsis theobromæ* n. g. and n. sp. is said to have been reared from the cacao bean at Pittsburgh, Pa.

The tobacco splitworm, A. C. MORGAN and S. E. CRUMB (*U. S. Dept. Agr. Bul.* 59 (1914), pp. 7).—Experimental rearings of the larvæ of the potato-tuber moth on tobacco, etc., and of the tobacco splitworm on potato tubers, etc., have shown that there is no perceptible difference in the period of development, in habits, or in the behavior of the two forms on a given food plant that could be ascribed to the different origins of the individuals. The known food plants

^a *Rev. Vit.*, 35 (1911), p. 39.

of *Phthorimæa operculella* include *Solanum torvum*, *S. verbascifolium*, *S. carolinense*, *S. nigrum* (?), eggplant, potato, tomato, *Physalis peruviana*, *Physalis* sp., *Physalodes physalodes*, *Datura stramonium*, and tobacco. In 1908 it was the cause of an injury to shade-grown tobacco in Dade County, Fla., to the extent of \$12,000 on 80 acres.

The larva occurs both as a borer and as a leaf miner, the former probably being the original habit, examples of which have been observed in the fruit of eggplants, in tomatoes, and in the stems of tobacco. In Sumatra this is the more common form of injury to tobacco, the larva forming a gall in the stem, and a similar habit of the larva has been observed in the Transvaal.

Only the older tobacco leaves are affected unless the infestation is very severe, and in these, the lower leaves, grayish, irregular blotches are produced, which later turn brown and become fragile, so that the tobacco is unfit for wrappers. In Tennessee the splitworm requires from 25 to 30 days in summer for completing its development from egg to adult. "Of this time 4 days are spent in the egg stage, 15 to 17 days in the larval stage, and 6 to 9 days in the pupal stage. The length of these stages is considerably affected by temperature. . . . Eggs are deposited singly upon the foliage of the host plant. Moths begin to oviposit 2 or 3 days after emergence and continue ovipositing for several nights. The largest number of eggs obtained from a single moth was 46, but this probably does not represent the maximum oviposition under normal conditions. . . . The larva pupates in a slight but somewhat tough cocoon of silk and débris among clods or rubbish at or near the surface of the soil. . . .

"Full-grown larvæ have been received from Florida in late April, indicating that oviposition may begin in that region as early as March. Larvæ have not been found at Clarksville, Tenn., earlier than June 3, and moths have emerged in numbers as late as the middle of November. It seems probable that at least 6 generations are produced in Florida and that about 3 or 4 are produced at Clarksville, Tenn. Moths emerged in 5 cages at Clarksville November 14, 1913, and were still active December 15, upon which date about an equal number of cages still contained pupæ. These records seem to indicate that the winter is passed in both the pupal and adult stages. No larvæ, so far as known, have entered hibernation successfully." It is stated that about 25 per cent of the full-grown larvæ of a large shipment of splitworms that came from North Carolina in August, 1913, were parasitized.

Remedial measures consist of the destruction of the larvæ in the mines by pinching and the destruction of all trash in and around tobacco fields and tobacco barns by burning. In severe infestations it may be necessary to prime off and destroy the leaves infested by the earlier generations.

Coccobacillus parasites of insects, A. PAILLOT (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 15, pp. 608-611).—The name *Bacillus gortynæ* is given to an organism isolated from caterpillars of *Gortyna ochracea*, an artichoke pest, during the course of an epidemic among them in the Department of Var, France. Microscopic examination of the blood and tissues of caterpillars of *Pyrameis* (*Vanessa*) *cardui*, which devour the leaves of artichokes, showed the presence of 2 different coccobacilli to which the names *B. pyrameis* I and *B. pyrameis* II are given. The author finds it difficult to determine whether the coccobacilli are distinct or merely varieties of a single species. He suggests that these may represent one or more saprophytic species, widespread in nature, which are readily adaptable to a parasitic life.

Culicoides kiefferi n. sp., a new Indian bloodsucking midge, W. S. PATTON (*Indian Jour. Med. Research*, 1 (1913), No. 2, pp. 336-338, pl. 1).—Cattle are said to be the chief hosts of this hematophagous dipteran.

The life of the fly, J. H. FABRE (*New York, 1913, pp. 477*).—A popular work containing a translation of all the essays on Diptera from the author's *Souvenirs Entomologiques*.

The Syrphidæ of Ohio, C. L. METCALF (*Ohio State Univ. Bul., 17 (1913), No. 31, pp. 123, figs. 255*).—This paper treats of the subject in three parts.

The first (pp. 12–52) consists of a general discussion of the family; general characters of the egg, larva, pupa, and adult; an evolutionary table of larval habits; biological and ecological relations and economic importance of the larvæ; ecological relations and economic importance of the adults; enemies; and practical measures. The second part (pp. 52–74) consists of a key to known larvæ of Syrphidæ; synopses of life history studies of 10 species, several of which have been previously noted (*E. S. R., 29, p. 456*); and a generic review of the literature on the biology of Syrphidæ. The third part (pp. 74–100) consists of a key to the genera of Syrphidæ; list of Ohio species with keys to the species and various genera which have been, or are likely to be, collected in the State; and a bibliography of 23 titles.

Fruit flies of Fiji, J. F. ILLINGWORTH (*Hawaii. Forester and Agr., 10 (1913), No. 12, pp. 366–370*).—Four species of fruit flies of the genus *Dacus* have been reared from fruit in the Fiji Islands, namely, the Fiji fruit fly (*D. passifloriæ*), from granadilla fruits and mangoes; the pineapple fruit fly (*D. xanthrodes*); the South Sea guava fly (*D. psidii*); and the banana fruit fly (*D. curvipennis*).

The occurrence of the warble fly, Hypoderma bovis, in Canada, C. G. HEWITT (*Canad. Ent., 46 (1914), No. 1, pp. 1, 2*).—The author reports records of the occurrence of *H. bovis* which show it to be widely distributed in Canada from the Atlantic to the Pacific.

Flies in relation to disease.—Nonbloodsucking flies, G. S. GRAHAM-SMITH (*Cambridge, England, 1913, pp. XIV+292, pls. 24, figs. 32*).—In the preparation of this book the author has attempted to collect the most important and reliable information available on the subject. In addition to accounts of the anatomy and biology of flies, methods employed in studying them, bacteriology and ways in which bacteria are distributed, and their relation to specific diseases, he discusses the part played by flies in the dispersal of the eggs of parasitic worms, myiasis, diseases, parasites, and enemies of flies, flies breeding in or frequenting human feces, and prevention and control of flies.

A bibliography of 17 pages and author and subject indexes are included.

The conservation of pathogenic bacteria by flies during hibernation, V. BÉRÉSOFF (*Russ. Vrach., No. 26 (1913), pp. 917–921; abs. in Presse Méd. [Paris], No. 93 (1913), p. 939*).—Studies were made of 150 flies collected in St. Petersburg hospitals after a hibernation of from 4 to 5 months. After having been washed in a sublimate solution to destroy all micro-organisms on the surface of the body, cultures were made from the digestive tube which showed the presence of *Staphylococcus pyogenes albus*, *S. pyogenes aureus*, *Proteus mirabilis*, *Bacillus coli*, and three additional varieties of *S. pyogenes*. The intraperitoneal injection of a culture of one of the streptococci killed a mouse in 24 hours. In addition to the above mentioned species the author isolated a large number of micrococci and bacilli nonpathogenic for man, and also 5 micro-organisms which did not appear to have been previously described. Thus the investigations show that a large number of pathogenic micro-organisms are conserved alive in the flies during hibernation.

Hydrotaea dentipes, its biology and the destruction by its larvæ of the larvæ of Musca domestica, I. A. PORTCHINSKY (*Trudy Būro Ent. [St. Petersburg.], 9 (1913), No. 5, pp. 30, figs. 23; abs. in Rev. Appl. Ent., 1 (1913), Ser. B, No. 9, pp. 149–152*).—The author here reports studies of *H. dentipes*

and its relation to other species of coprophagous flies. The investigations show the larvæ of *H. dentipes*, which become predaceous upon reaching the third stage, to be very destructive to the larvæ of the house fly and stable fly.

In experiments to determine the relations existing between the larvæ of *H. dentipes* and those of *Polyetes abolineata*, which are the most rapacious of all coprophagous larvæ, it was found that the resistance of the former was usually fierce and persistent, but never successful. The larvæ of *H. dentipes* were never observed to attack each other even when their food was scarce, although such cannibalism is often practiced by larvæ of *Myospila mediatubunda* and *P. abolineata*. *H. dentipes* is very prolific, depositing 170 to 200 eggs which mature at about the same time. The larvæ travel very rapidly, are omnivorous feeders, and will live on all materials which serve as breeding places for the house fly. It is said that *H. dentipes* visits human dwellings. In observations in the district of Tzarskole Selo, the author found no larvæ of the stable fly and but few of the house fly, but the larvæ of *H. dentipes* were always abundant. In his opinion *H. dentipes*, in addition to other parasitic insects, is chiefly instrumental in preventing the multiplication of *Musca domestica* which otherwise would become a great pest.

Observations of the insect fauna of the southern part of the Government of Stavropol (North Caucasus), made during July and August, 1911, are described.

Empusa muscæ as a carrier of bacterial infection from the house fly, R. M. BUCHANAN (*Brit. Med. Jour.*, No. 2760 (1913), pp. 1369-1372, pls. 2, figs. 6).—The author finds that when house flies, parasitized by the fungus *E. muscæ*, are collected on fly paper that they become a center from which the spores of the fungus are showered in numbers sufficient to whiten other flies stuck fast on the paper in close proximity. He reports investigations made with a view to determining whether or not the spores carry with them bacteria from the body of the fly, if infective organisms from the interior of the fly are disseminated in this manner.

Though the manner in which the fungus gains entrance to the body of the fly is not definitely known, it has usually been stated as occurring through the germination of a spore that has become attached to the surface of the insect and the penetration of the resulting hyphal filament through the body wall. Flies examined by the author, however, gave no microscopical evidence in support of this view as to entrance through the abdominal and thoracic walls. The fungus permeates the entire body, even the legs and antennæ, but in doing so it has always presented certain definite characteristics of localization and form, as are described by the author. The majority of the flies presented great numbers of bacteria in the intestines, and among the hyphæ of the abdominal cavity they were widely distributed, spreading toward the abdominal wall. Though the manner in which this fungus persists from year to year is not known, the formation of resting spores would serve to explain this hiatus in the life history of the fungus, but the existence of such bodies has not yet been definitely determined. On the other hand, the author found upon examination of the eggs from a diseased fly that some of the mycelium remained firmly attached to the outer covering or chorion. Thus the deposition of eggs by a fly harboring the fungus renders it extremely likely that the larvæ would in turn become infected.

In order to determine whether the conidia in their outward course carry bacteria from the fly to the surface upon which they are projected, 10 flies were fixed head downward upon nutritive agar in the center of a Petri plate, with the uniform production of a zonal crop of colonies. Detailed examinations of the first five plated showed that the colonies numbered from 70 to 400 and that their distribution was well within the farthest range of the conidia. By the

usual fermentation tests the colonies were proved to be almost entirely representative of groups in the colon family. One fly supplied four types of coliform bacilli, two gave two each, and two one each. The results are representative in some measure of the intestinal flora of the house fly, as found by several investigators, and also representative of bacteria which may be found in the human intestine.

Since *E. muscæ* proves to be a potential means of bacterial dissemination not hitherto recognized, its use as a means of reducing or exterminating the house fly is regarded as an expedient of doubtful value.

In the author's observations the proportion of diseased to apparently sound flies was small. The fungus showed itself almost entirely in *Musca domestica*, only two parasitized flies of the species *Fannia canicularis* being discovered.

A bibliography of 25 titles is included.

On the predaceous habits of Scatophaga: A new enemy of Musca domestica. C. G. HEWITT (*Canad. Ent.*, 46 (1914), No. 1, pp. 2, 3).—The author reports observations of the habit of *Scatophaga stercoraria* of feeding upon the house fly, *Calliphora erythrocephala*, *Stomoxys calcitrans*, *Fannia canicularis*, *Pollenia rudis*, and *Orthellia cornicina*. Its preference for muscid flies is said to be noticeable. "After seizing their victims, they wrapped their legs around them and the neck of the victim was then pierced from below by thrusts of the proboscis and sucked for a short time. The body was afterwards turned over and the proboscis inserted between the abdominal segments, in which position the fly continued to feed for a long time. In some cases, for example *P. rudis*, the victim's head was completely broken off."

Little brown ant doing good work in Hawaii. J. F. ILLINGWORTH (*Hawaii. Forester and Agr.*, 10 (1913), No. 12, pp. 370, 371).—The author's investigations indicate that *Pheidole megacephala* is the principal factor holding house flies in check in Fiji and Hawaii, it being estimated that fully 75 per cent of the flies in Hawaii are destroyed. The ants even attack and destroy the full-grown maggots whenever they appear on the surface of the manure.

The flea. H. RUSSELL (*Cambridge, England, 1913*, pp. VII+125, pl. 1, figs. 8).—This is a small popular handbook on the flea, its anatomy, habits, relation to bubonic plague, bibliography, etc.

Root borers and other grubs in West Indian soils. H. A. BALLOU (*Imp. Dept. Agr. West Indies Pamphlet* 73 (1913), pp. 38, pl. 1, figs. 20).—This pamphlet consists of a selection of insect notes, previously noted from another source (*E. S. R.*, 29, p. 858), to which illustrations have been added.

The grass grub pest. A. P. W. THOMAS (*New Zealand Dept. Agr., Indus., and Com. Bul.* 27, n. ser. (1913), pp. 14).—This paper presents an account of the natural history of grass grubs of the genus *Odontria*, recent observations thereon, and methods of prevention.

The acclimation of Novius cardinalis in France. P. MARCHAL (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 15, pp. 561-564).—The author reports that sendings of this lady beetle from Italy, Portugal, and the United States have resulted in its establishment in the section of France, which has recently become infested by *Icerya purchasi*.

Parallelism in morphological characters and physiological characteristics in scolytid beetles. A. D. HOPKINS (*Proc. Biol. Soc. Wash.*, 26 (1913), pp. 209-211).—This is an abstract of a paper read before the Biological Society of Washington, D. C., November 29, 1913.

Bees: Feeding and feeders. F. A. JACOBSEN (*New Zealand Dept. Agr., Indus., and Com. Bul.* 39, n. ser. (1913), pp. 8, figs. 3).—A brief popular account.

The occurrence of the Australian cattle tick and the brown dog tick in Key West, Florida (Acarina, Ixodoidea). F. C. BISHOPP (*Ent. News*, 24

(1913), No. 8, pp. 366–368).—The Australian cattle tick (*Margaropus annulatus australis*) is reported to have been collected on native cattle at Key West, Fla., in February, 1912. The brown dog tick (*Rhipicephalus sanguineus*) was taken from dogs and a donkey at the same time. The author points out the importance of ridding Key West of this pest, which in addition to transmitting Texas fever attaches itself to a much larger variety of hosts than does our native cattle tick.

Researches on the embryonic development of nematode parasites, A. MARTIN (*Ann. Sci. Nat. Zool.*, 9. ser., 18 (1913), No. 1–2, pp. 151; *abs. in Rev. Gén. Méd. Vét.*, 22 (1913), No. 264, pp. 689–692).—This work reports studies made of the development of eggs of *Ascaris vitulorum*, *A. suis*, *A. canis*, *A. equorum*, *A. lumbricoides*, *Heterakis columbæ*, *Trichocephalus depressiusculus*, *Sclerostomum equinum*, and *S. vulgare*. The first part (pp. 5–77) relates to experimental development of the eggs of several species; the second part (pp. 79–128) to a critical study of the factors influencing the development of the eggs; and the third part (pp. 129–146) to the application of experimental results under conditions existing in natural infestation. A bibliography of 49 titles is appended.

Ktenol, A. GRÉGOIRE (*Min. Agr. et Trav. Pub.* [Belgium], *Off. Rural Raps. et Communs.*, No. 7 (1913), p. 52).—A complete analysis is given of this insecticide.

FOODS—HUMAN NUTRITION.

The baking qualities of flour as influenced by certain chemical substances, milling by-products, and germination of the wheat, J. T. WILLARD and C. O. SWANSON (*Kansas Sta. Bul.* 190 (1913), pp. 237–285, figs. 8).—Experimental methods are described at length and data reported in which the influence on bread making of different chemicals and substances in the by-products of milling was studied.

The chemical substances included among others peptones; glycocoll; leucin; aspartic acid; asparagin, ammonium acetate, tartrate, chlorid, and phosphate; sodium phosphate, bicarbonate, and formate; and potassium nitrate. The substances contained in the milling products included cold water extract of bran, filtered and unfiltered, hot water extract of bran, extracts of wheat scourings, flour from germinated wheat, cold water extract from the bran of germinated wheat, boiled extract from bran of germinated wheat, and cold water extract from the shorts of germinated wheat.

In general, the authors note that the addition of these materials caused no marked increase or decrease in the time of the first rise of the dough. In the case of the second rise the results were more pronounced, the period being markedly shortened with most of the substances used. "The sodium and potassium compounds did not affect the result either way, but the heated bran extract and the cold extract from the shorts of germinated wheat showed a distinct lengthening of the period. The boiled bran extract from germinated wheat also showed the same tendency as far as the trial was comparable with the others."

Considering the amount of rise of the dough as a whole, the authors note that "as a class the amino compounds showed a tendency to decrease the maximum volume of the dough, while the ammonium compounds showed no such tendency as a group. Also the bran extracts from sound bran showed no decrease, while the various products from germinated wheat showed a distinct decrease. . . . The amino compounds and ammonium compounds, as well as the various products obtained from sound and modified wheat, decreased the

time of rising in almost all cases. . . . The time for rising may be shortened through two causes: Either the presence of a food which stimulates the activity of the yeast, or a weakening of the gluten so that the same amount of yeast activity will accomplish the same result in a comparatively shorter time. In this latter case we are likely to have less maximum amount of rise in the dough than in the former case where the substance stimulates the yeast activity without affecting the quality of the gluten. An examination of the figures for the time of rising and comparing them with the maximum rise of dough would show that the amino compounds as a class, whether used as pure chemicals or as found in germinated wheat products, affect the gluten in an unfavorable way. On the other hand, substances which furnish food for the bacteria, such as the ammonium compounds and the extracts from sound bran, stimulate yeast activity without injuring the quality of the gluten. This opens up a very interesting and profitable line of investigation in regard to the different ways the gluten may be affected by the various methods of handling and storing wheat, as well as the chemical compounds which are the ultimate cause of the baking qualities of different flours."

The data reported with respect to spring in the oven and loaf volume do not show any concordance and are not uniform enough so that definite conclusions can be drawn from them, though they do not contradict the conclusions noted above.

With respect to the texture of the crumb the amino compounds, with few exceptions, had an unfavorable effect. "The amino compounds present in modified wheat products were the most pronounced in this respect. On the other hand, with a few exceptions, the ammonium compounds as well as the extracts from sound bran had no unfavorable effect on texture. Amino compounds as a class are unfavorable to the baking qualities of the flour. As a group they are more pronounced in their effects than the proteins such as gliadin, glutenin, edestin, or leucosin. It seems safe to conclude that a study of wheat flour along these lines would be more profitable than many of the methods hitherto used."

Tests were also made to ascertain the effects of adding starch, bran, or bran extract to flour in bread making. The addition of starch, it is noted, would act in a way as a diluent, neither increasing or decreasing the amount of gluten and has the same effect as a decrease of the percentage of protein without any change in its quality.

"There was a regular shortening of the total time for rising, being longest for the check loaf and shortest for the loaf where bran extract was used. . . . The presence of starch diminished the total expansion, oven spring, and loaf volume as compared with the check loaf. The texture was not impaired by the presence of starch but was equal to the check loaf. The use of bran diminished in a larger measure the total expansion, oven spring, and loaf volume. This loaf had the least total expansion and loaf volume. The texture was also poorest in this loaf. It is remarkable that the cold extracted bran should differ in so marked a degree from the nonextracted bran. The oven spring, total expansion, and loaf volume were so much larger in every case that the result can not be due to accidents, and the same results were obtained in the second trial. The total expansion, oven spring, and loaf volume were somewhat less with the hot extracted bran than with the cold extracted bran. The effect of the cold bran extract was, in the main, the same as when this substance was tried before. It had the shortest total time for rising, the largest total expansion, oven spring, and loaf volume in this test [and a little better texture].

The authors discuss the data and raise the question as to whether bran mixed with dough without previously wetting acts merely as so much inert matter, and whether or not a better graham bread would be obtained if the bran were mixed with water and allowed to soak for some time before adding it to the flour. See also previous notes (E. S. R., 29, p. 863; 30, p. 164).

Corn meal as a food and ways of using it. C. F. LANGWORTHY and CAROLINE L. HUNT (*U. S. Dept. Agr., Farmers' Bul. 565 (1914), pp. 24*).—The origin and composition of Indian corn are discussed, as well as corn meal, methods of milling it, and its nature and uses, the relation of corn meal to the balanced ration, the combination of corn meal with more highly flavored foods, cookery of corn meal, and similar questions.

A large number of recipes collected from various sources and standardized are given for corn-meal mushes and similar dishes, corn meal and meat dishes, corn-meal bread, corn-meal puffs, griddlecakes, and waffles, corn-meal puddings, and corn-meal cakes. A portion of these have been previously noted (E. S. R., 29, p. 864.)

In preparing the bulletin experimental studies were made of the subjects under consideration, and the recipes were studied by laboratory methods.

It is pointed out that the purpose of the bulletin is not to recommend Indian corn to the exclusion of other cereals, but "to speak of its value as a food and its distinguishing qualities which call for special methods of cooking, and to show how it may be used to secure variety in one of the principal lines of food materials which make up the usual dietary. . . .

"Corn meal compared with other foodstuffs of a similar nature is a low-priced food material, and when used alone or with other equally low-priced foods make economical dishes.

With reference to the use of corn meal ground in different ways, the following statement is made:

"Since the composition of the new-process meal differs from that of the old-process meal in having less fat as well as less water, it is desirable to make allowance for this when using the new meal. In making such simple dishes as hoecake and corn-meal pone, which originally were prepared from the meal and water alone, a little lard or butter should be added and in other dishes the allowance of fat should be slightly increased."

The importance of maize as human food. O. RAMMSTEDT (*Ztschr. Öffentl. Chem.*, 19 (1913), Nos. 15, pp. 288-294; 16, pp. 305-316; 17, pp. 327-334).—The author reviews the literature of maize and its methods of use in different parts of the world, reports original analyses, and advocates the more extended use of the cereal in Germany and its greater cultivation in the German colonies.

Immense value of rice as a food. L. M. BRIGGS (*Gulf States Farmer*, 7 (1913), No. 12, p. 11).—A popular article containing a few statistics of rice consumption and recipes for rice dishes.

Investigations of the nutritive value of Finnish rye bread. O. VON HELLENS (*Skand. Arch. Physiol.*, 30 (1913), No. 4-6, pp. 253-284).—The author carried on digestion experiments with normal subjects living for from 2 to 3 days on diets of different types of rye and famine breads with butter and tea. The results indicate that the losses through the feces increased in proportion to the amount and coarseness of the cellulose present.

Aguman—a new nutritive meal made from the soy bean. R. KAFEMANN (*Umschau*, 17 (1913), No. 50, pp. 1041-1043).—The preparation here referred to is described as an easily soluble powder of pleasant flavor which may be consumed in water, milk, or other liquids, used as the basis of soup, or made into bread or cake.

Chemistry and mycology of the fruit of *Cicer arietinum*, A. ZLATAROW and S. STOIKOW (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 5, pp. 242-247; *abs. in Chem. Zentbl.*, 1913, II, No. 18, pp. 1607, 1608).—A progress report of analyses of a common Bulgarian variety of the chickpea, both in the raw state and in the roasted form called "Leblebiji", with special reference to the amount and forms of phosphorus present.

Contribution to the question of judging the meat of tuberculous cattle as regards its use as food, C. TITZE, H. THIERINGER, and E. JAHN (*Arb. K. Gsndhtsamt.*, 45 (1913), No. 3, pp. 364-424, pls. 6).—Recent investigations along the line of this subject are reviewed, and original work is reported, but the authors do not as yet feel justified in making direct practical application of their results.

Herring salts, P. BUTTENBERG (*Mitt. Deut. Seefisch. Ver.*, 29 (1913), No. 3, pp. 74-83; *abs. in Hyg. Rundschau*, 23 (1913), No. 22, p. 1416).—The chemical composition and physical characteristics of different types of salt such as are commonly used in Germany for curing herring are here noted.

Concerning methods of making coffee, O. W. WILLCOX (*Pure Products*, 9 (1913), No. 12, pp. 611-615).—Experimental data are reported and summarized, and tests by E. Aborn are also briefly reported.

According to the conclusions drawn, boiling gave the greatest amount of extract (strong coffee), the solution containing a relatively high amount of caffeine and caffetannic acid. "Steeping gives a lower amount of caffeine than boiling but quite as much caffetannic acid. When operating with coffee of medium granulation, steeping seems to yield the least amount of caffeine than any other method. Filtration gives less extract than boiling or steeping and gives less caffetannin than any other method. Scalding gives results intermediate between filtration and boiling.

"Percolation gives a low extract, but high caffetannic acid and high caffeine. The reason why percolation gives such results is probably because the water in the percolator is never exactly at the boiling point, and it seems from the work of others that actually boiling water is necessary to dissolve some of the soluble matters of the coffee. The caffetannic acid and caffeine, however, being readily soluble in cold water, seem to be dissolved with great facility in the percolation method, especially in view of the fine granulation used in brewing coffee in the percolating method."

According to the author, uniformity of quality in domestic coffee making depends upon accuracy in measuring the proportion of coffee and water and always having the water at exactly the same temperature, "which can always be done by making sure that it is boiling vigorously before the coffee is added," and by regulating the time in which the grounds remain in contact with the water.

Lemon essence, L. WOLFRUM and J. PINNOW (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 8, pp. 409-422).—A description of analytical methods and a definition of a standard for lemon essence from the state chemical laboratory in Bremen.

Report of the bureau of food and drugs, M. E. JAFFA (*Bien. Rpt. Bd. Health Cal.*, 22 (1911-12), pp. 272-304).—This third biennial report of the director of the state food and drugs laboratory includes a statement of work done with miscellaneous food products, beverages, water, and drugs. A summary of analytical work is appended.

State of Michigan Dairy and Food Department (*Mich. State Dairy and Food Dept. Bul.* 214-15 (1913), pp. 44, pls. 5).—Besides reports of food and drug analyses, dairy inspections, and miscellaneous notes, this bulletin contains a description of the special demonstration train in which the educational

exhibits of the Michigan State Dairy and Food Department and Board of Health were displayed throughout the State.

The proposed changes in the food law, A. JUCKENACK (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 26 (1913), No. 10, pp. 488-497).—An address delivered at the twelfth general meeting of the Union of German Food Chemists held at Breslau, June, 1913. The officially proposed changes in the present German law regarding food inspection and the punishment of the sale of adulterated or injurious food materials are discussed, and the resolutions adopted in regard to them by various associations of food manufacturers, etc., are quoted and commented on.

The bleached flour decision, R. A. GORTNER (*Biochem. Bul.*, 2 (1913), No. 8, pp. 532-534).—A controversial article.

Supplement to the discussion of foods and medicines of the ancient Egyptians, F. NETOLITZKY (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 26 (1913), No. 8, pp. 425-427).—This article contains notes on present day Egyptian food customs similar to those believed to have been practiced in antiquity. Several forms of preserved fish are described, which appear to be not unlike the garum of the ancient Romans.

The cost of living (*Philadelphia, 1913*, pp. VI+265).—This volume is a collection of papers delivered before the American Academy of Political and Social Science, the four general topics being wage standards, family standards, public services and control, and concrete measures for reducing cost of living. Among the individual articles may be mentioned the following: Scientific Management in Home Making, by Mrs. F. A. Pattison; Utilization of the Family Income, by Mrs. Martha B. Bruère; Municipal Markets in their Relation to the Cost of Living, by C. C. Miller; Communal Benefits from the Public Control of Terminal Markets, by Mrs. E. Black; Relation of Cold Storage to the Food Supply and the Consumer, by Mary E. Pennington; and The Housekeeper and the Cost of Living, by Martha Van Rensselaer.

Keeping down the cost of living in Germany, G. N. IFFT (*Daily Cons. and Trade Rpts. [U. S.]*, 16 (1913), No. 270, pp. 894, 895).—The high cost of meats has led to the establishment of municipal markets in Nuremburg where without loss to the city prices are about 25 per cent below those of the retailers.

In order to encourage the use of fish in the place of meat, municipal fish markets have also been established. Free lessons in cooking fish have been given both in the continuation schools for girls and in special weekly courses for housewives, and, in connection with the latter, books of fish recipes have been distributed.

The art of bill of fare making, CAROLINE L. HUNT (*Dakota Farmer*, 33 (1913), No. 23, pp. 1125, 1126).—A summary of an address given at the International Dry Farming Congress, Tulsa, Okla., October, 1913. The work of the U. S. Department of Agriculture for women is briefly outlined and planning an adequate menu is discussed. Various foods are classified and a basis of selection suggested, comparing other foods as sources of protein with an egg as a standard.

Recipes and menus for fifty as used in the school of domestic science of the Boston Young Women's Christian Association, FRANCES L. SMITH (*Boston*, 1913, pp. X+246).—Although this compilation of recipes was published primarily for the use of the author's students, she considers it also of practical value to others concerned with the preparation of food for large numbers of persons. As she points out, the amounts indicated are intended for women at light muscular work and, therefore, may need modification for persons of other dietary requirements.

General recipe book for bakers and confectioners, L. A. ROSSWAAG (*Allgemeines Rezept-Buch fuer Bäcker und Conditoren. New York, 1913, vol. 1, 5. ed., enl., pp. 128*).—This handbook, intended evidently for the use of German professional cooks in the United States, includes numerous recipes for cakes, cookies, frostings, and other sweet dishes.

Camp cookery, AVA B. MILAM and RUTH McN. SMITH (*Oreg. Agr. Col. Bul. 76 (1913), pp. 47, fig. 1*).—Camp food supplies, ration lists (including a sustenance table prepared by the Forest Service of the U. S. Department of Agriculture giving the amounts of different articles of food required per day for 1 to 10 men), camp equipment, and similar topics are discussed, and a large number of recipes given for preparing camp dishes, including bread, meats, vegetables, and pastry.

Agricultural publications as aid to the housekeepers—how they may be obtained, CAROLINE L. HUNT (*Gen. Fed. (Women's Clubs) Mag., 11 (1913), No. 15, pp. 15, 16*).—Information is summarized regarding the publications of the U. S. Department of Agriculture of interest to housekeepers.

How to obtain home economics information, HELEN L. JOHNSON (*Gen. Fed. (Women's Clubs) Mag., 11 (1913), No. 15, pp. 14, 15*).—Suggestions are made regarding sources of information, particularly the publications of the U. S. Department of Agriculture and other government departments.

The statistical study of dietaries, K. PEARSON (*Biometrika, 9 (1913), No. 3-4, pp. 530-533*).—A critical study of the recent investigation by Dorothy E. Lindsay into dietary conditions among laboring classes in Glasgow (*E. S. R., 29, p. 464*), special emphasis being laid on the desirability of anthropometric measurements in such work.

Further investigations regarding digestion and resorption under normal and pathological conditions, E. S. LONDON ET AL. (*Hoppe-Seyler's Ztschr. Physiol. Chem., 87 (1913), No. 5-6, pp. 313-370*).—A brief summary of the results of a long series of experiments (*E. S. R., 20, p. 662*) designed to throw light on the different phases of digestion and metabolism. Surgical methods of altering the course of digestion were frequently used.

The influence of butter fat on growth, T. B. OSBORNE and L. B. MENDEL ET AL. (*Jour. Biol. Chem., 16 (1913), No. 3, pp. 423-437, figs. 5*).—In experiments previously noted (*E. S. R., 30, p. 64*) it was found that young rats which for a time grew at a normal rate on a "protein-free milk" diet sooner or later ceased to grow, and, furthermore, that they recovered and resumed their normal rate of growth when a part of the lard in their food was replaced by a corresponding quantity of unsalted butter. The authors' conclusion that butter supplied some substance which exercises a marked influence on growth has been substantiated by additional experiments which are summarized.

In view of the possibility that even an extremely minute quantity of some substance might be responsible for the favorable influence noted, the butter was separated into three parts, namely, the fatty substances, the insoluble solid elements, and the aqueous solution containing lactose, soluble inorganic salts, and other soluble components of the milk. The feeding trials showed that the growth-promoting factor was contained in the fat fraction, so the other fractions were not considered further.

In discussing the experimental data summarized, the authors state that it appears improbable "that glycerids of the fatty acids ordinarily present in foods are responsible for the promotion of the growth observed when butter fat replaces lard in the diet of rats which have ceased to grow. Lecithin and other phosphorus- or nitrogen-containing substances are excluded by the absence of phosphorus and nitrogen from our butter fat; and cholesterol by the

fact that even more of this substance has been obtained from lard than from butter.

"So far as our experience has shown, the addition of butter fat to our natural 'protein-free milk' foods gives them an efficiency quite comparable with that of our milk food in promoting recovery and the completion of growth. The exact chemical differences between the adequate butter fat and the inadequate lard (which determine success and failure respectively in the food mixtures employed) are far from being satisfactorily known. Chemical examination of the butter fat indicates that the effective component is not a phosphatid or any inorganic substance, inasmuch as nitrogen, phosphorus, and ash are lacking in the product employed. It is suggestive to note that in the one case (lard) we are dealing essentially with a fat mixture deposited in storage depots of the animal organism; in the other, the butter fat represents the product of metabolic activity and synthesis on the part of the cells of the mammary gland. What, if anything, this distinction between cellular product and reserve fat may mean physiologically, remains to be investigated.

"The researches which have been devoted in recent years to certain diseases, notably beri-beri, have made it more than probable that there are conditions of nutrition during which certain essential, but, as yet, unknown substances must be supplied in the diet if nutritive disaster is to be avoided. These substances apparently do not belong to the category of the ordinary nutrients, and do not fulfill their physiological mission because of the energy which they supply. Funk [E. S. R., 28, p. 261] has proposed the name vitamin for the type of substance thus represented.

"Without minimizing the importance of the new field of research and the new view points in nutrition which are presented by these recent findings, we may nevertheless hesitate to accept the extreme generalizations which have already been proposed on the basis of the evidence obtained largely from the investigation of pathological conditions. . . . It is still rather early to generalize on the rôle of accessory 'vitamins' when the ideal conditions in respect to the familiar fundamental nutrients and inorganic salts adequate for prolonged maintenance are not completely solved. Speculation is quite justifiable in so far as it directs attention to a new phase that needs to be taken into account.

"Funk has expressed the belief that the substance which promotes growth and must be present in order to avert the cessation of growth, which we have described to occur after a certain period of successful growth on our earlier dietaries, is either identical with, or analogous to, the 'vitamin' which plays the rôle of an antiscorbutic substance. For this we can as yet find no compelling evidence. Certainly the nitrogen-free butter fat, so successful in remedying our growth failures, contains no substance chemically related to the nitrogenous products which have lately been credited with this unique physiological efficiency. . . .

"Butter fat has shown a further interesting nutritive superiority over lard. At certain periods of the year, particularly in summer months, we have frequently failed to secure satisfactory growth on the dietaries which proved adequate during the usual period of 60 to 100 days at other seasons. Occasionally young rats in the stock colony have exhibited a similar 'epidemic' of poor growth at the same season. The failures are, however, not common to rats fed on the milk food; and we have lately observed that the seasonal failure is also averted by the addition of butter fat to the usual 'protein-free milk' food mixtures. Again, another type of nutritive deficiency exemplified in a form of infectious eye disease prevalent in animals inappropriately fed is

speedily alleviated by the introduction of butter fat into the experimental rations.

"The chemical character of the unique 'accessory substance' in butter fat must be investigated in detail and its possible presence elsewhere determined. Experiments are already under way with varying proportions of butter fat in the ration; but we have not thus far determined the necessary allowance. On the other hand, no amount of butter fat will induce growth on certain dietaries in which the proportions and nature of the inorganic salts are inappropriate . . . , or the quantity and character of the protein are inadequate."

In a supplementary note brief reference is made to experiments undertaken to determine the possible efficiency of fats other than butter fat in preventing decline on the protein-free milk food used and promoting growth. Marked differences in fats from different sources have been found. Egg yolk, for example, appears to behave like butter fat, while some other fats have thus far proved no more efficient than lard.

"Such considerations make it evident that the comparative value of the natural fats employed in nutrition must be determined, as well as the individual rôle of the different proteins, carbohydrates, and mineral nutrients."

Metabolism of mineral matters, R. BERG (*Pharm. Zentralhalle*, 54 (1913), No. 47, pp. 1212-1216).—From clinical observations and theoretical considerations, and on the basis of extensive analysis of the mineral content of various food materials (*E. S. R.*, 29, p. 366), the author formulates the principle that a healthful and adequate diet must contain sufficient inorganic bases to neutralize the inorganic acids present in the food or formed during metabolism, and indicates food materials which may be advantageously used to accomplish this result.

Metabolism of fasting infants, A. SCHLOSSMANN and H. MURCHHAUSER (*Biochem. Ztschr.*, 56 (1913), No. 5-6, pp. 355-415, figs. 12).—Infants accustomed to bottle feeding were given water sweetened with saccharin in the place of their usual food for periods of from 30 to 76 hours, and the effects on body changes, and, in a few cases, on respiration were noted. The data for nitrogen metabolism and acetone and β -oxybutyric acid are given in detail, but no general conclusions were drawn.

Investigations of the presence and distribution of manganese in animal organs, G. BERTRAND and F. MEDIGRECEANU (*Ann. Inst. Pasteur*, 27 (1913), No. 1, pp. 1-11; *abs. in Hyg. Rundschau*, 23 (1913), No. 22, p. 1411).—Small quantities of manganese ($\frac{1}{100}$ to $\frac{1}{10}$ mg. per 100 gm. fresh material) were found in all the organs and secretions of the 15 types of vertebrates examined, except in the whites of birds' eggs. The differences in the proportions of manganese found in different parts of the same animal were greater than in the same organs of different animals. In general, manganese was more abundant in birds than in mammals, and in liver, kidneys, hair, nails, and feathers, than in lung, nerve tissues, milk, and blood.

Investigations of the amount of manganese normally present in the blood, G. BERTRAND and F. MEDIGRECEANU (*Ann. Inst. Pasteur*, 26 (1912), No. 12, pp. 1013-1029; *abs. in Hyg. Rundschau*, 23 (1913), No. 22, pp. 1410, 1411).—In spite of accurate methods, the results of these studies according to the authors do not agree with those of previous investigators, but indicate much smaller quantities of manganese.

In normal human blood, as well as that of various domestic animals and birds, only from $\frac{1}{10}$ to $\frac{1}{100}$ mg. or less of manganese was found per liter. Twice as much was present in the red blood corpuscles as in the plasma.

The influence of manganese on metabolism is to be studied in future work.

Food as body fuel, H. P. ARMSBY (*Pennsylvania Sta. Bul.* 126 (1913), pp. 59-68).—The author discusses the animal as a prime motor, energy transformations in the body, and the origin of animal heat, and briefly summarizes his investigations and the work of others with reference to these questions.

The results presented, he concludes, may be taken "as demonstrating that the animal heat arises exclusively from the combustions in the body, but they have a much broader significance. They show that the transformations of chemical energy into heat and work in the animal body take place according to the same general laws and with the same equivalencies as in our artificial motors and in lifeless matter generally. The great law of the conservation of energy rules in the animal mechanism, whether in man, carnivora, or herbivora, just as in the engine. The body neither manufactures nor destroys energy. All that it gives out it gets from its food and all that is supplied in its food is sooner or later recovered in some form. We are fully justified, therefore, in speaking of the food as body fuel, and in our studies of its utilization we may be confident that any food energy which does not reappear in the form of heat or work has not been lost but has been stored up in the body as the chemical energy of meat, fat, etc., which may later serve to supply food energy to the human body when consumed as food by man."

The influence of nutrition on the gaseous metabolism of cold-blooded animals, B. ELSAS (*Ztschr. Biol.*, 62 (1913), No. 1-2, pp. 1-31; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 612, I, pp. 1126, 1127).—In the experiments here reported the inanition metabolism of laboratory animals (frogs) was first found by means of a modified Regnault-Reiset apparatus. In the later experiments amounts of fat and of protein equivalent to the inanition metabolism were fed and the effects of the respective diets noted.

Feeding fat did not increase the metabolism, but feeding protein raised it from 17 to 40 per cent. In the author's opinion, the work supports Rubner's theory of the specific dynamic action of different foodstuffs.

Note on the relationship between barometric pressure and carbon dioxid excretion in man, J. A. HARRIS (*Biochem. Bul.*, 2 (1913), No. 8, pp. 530, 531).—The formulæ here given were worked out from Higley's data (*E. S. R.*, 29, p. 569) regarding the product moment correlation method as applied to the question of barometric pressure on carbon dioxid excretion.

Chemical notes on ventilation, P. N. EVANS (*Proc. Ind. Acad. Sci.*, 1911, pp. 55-60; *Gesundhs. Ingen.*, 36 (1913), No. 36, pp. 669-671; *abs. in Zentbl. Biochem. u. Biophys.*, 15 (1913), No. 20-21, p. 848).—The author summarizes the results of his experiments as follows:

"It has been shown that under all ordinary conditions of ventilation the products of respiration move upwards; that this upward movement, by which the harmful products are removed from the level of respiration, is assisted by a low room temperature and by dryness of the air of the room; also, that the fresh air has the same density as expired air (saturated with moisture and at body temperature) at 33° C. or 91° F. if the fresh air is saturated with moisture, at 39° C. or 102° F. if perfectly dry, and at temperatures intermediate between these with different degrees of moistness."

An ergograph for the lower extremities, C. TIGERSTEDT (*Skand. Arch. Physiol.*, 39 (1913), No. 4-6, pp. 299-301, figs. 3).—In the apparatus here described the subject, seated on a bicycle saddle adjusted to a suitable position, presses with his foot upon one end of a lever, the other end of which is weighted. The distance which the weighted end rises is recorded by a needle attached at the fulcrum of the lever.

ANIMAL PRODUCTION.

Modern problems of biology, C. S. MINOR (*Philadelphia*, 1913, pp. IX+124, figs. 53).—This is a series of lectures delivered at the University of Jena dealing with the following subjects: The new cell doctrine, cytomorphosis, the doctrine of immortality, the development of death, the determination of sex, and the notion of life.

The general trend of development and inheritance problems, A. GREIL (*Richtlinien des Entwicklungs- und Vererbungsproblems*. Jena, 1912, vols. 1, pp. 352; 2, pp. 364).—These volumes are an enlargement on material previously reported (E. S. R., 27, p. 175).

Some phenomena of species hybridization among pheasants, G. P. MUDGE (*Anat. Anz.*, 45 (1913), No. 8-9, pp. 221-224).—It was observed that the first hybrid generation derived from a Silver female and a Swinhoe male "appears to manifest a translocation of a plumage character not only from the female sex of one of the parental species to the opposite sex of the hybrid, but from one body region of the female of the species to another body region of the opposite sex of the hybrid." It is also suggested that "not only does the male of a species transmit some of the secondary sexual characters of the female of his species, but that the female of a species may transmit those of the male." The same sort of translocation was observed in the second hybrid generation. The F₂ generation reproduced some F₁ hybrid features together with evidence of segregation of unit characters.

With regard to the 2 central retrices there was a transposition of color or pattern from the hen of one species to the cock of the hybrids, from the lateral retrices of the same species to the central retrices of the hybrid, and a reversal of orientation of pattern and of adjacent color areas. In the F₁ generation there was a transposition of the color characteristics of the primaries and secondaries of the Swinhoe hen to the male hybrid. In F₂ there was a complete segregation of one of the Swinhoe cock characters in one of the birds, in another a new character representing a somatic mosaic of the modified pattern of both parental cock species appeared, and in other members a remanifestation of the hybrid polymorphism shown in F₁ generation.

It is stated that conclusions drawn from these observations can only be tentative and provisional, awaiting further investigations along this line.

The establishment of a race of white canaries, MAUD S. MARTIN (*Sci. Amer. Sup.*, 76 (1913), No. 1982, pp. 410, 411).—A pure white hen canary, the sport offspring from ordinary buff parents and very much inbred, was mated with an unrelated buff cock. Three buff cocks and 3 buff hens were reared from this mating. These were then mated, producing 48 buff chicks and 18 white ones. Three buff hens from F₁ were mated to their sons, the white cocks of F₂ producing 14 buff chicks and 26 white ones. The 3 white hens from F₂ were mated to the white cocks F₂, producing 25 white chicks and no buffs, thus proving their recessive character. Six buff hens from F₂ were mated to white cocks of F₂, 2 of them giving only buff birds, presumably dominants; the other 4 having 16 buff and 27 white, evidently hybrids or impure dominants. A race of white canaries has thus been established which breed true to color and obey the Mendelian laws, producing dominants, hybrids, and recessives.

Tables for calculating coefficients of inbreeding, R. PEARL and J. R. MINER (*Maine Sta. Bul.* 218 (1913), pp. 191-202).—This bulletin furnishes tables for the calculation of coefficients of inbreeding, described and explained in a former publication (E. S. R., 30, p. 66).

"These tables make it possible for any farmer or breeder to analyze the pedigree of his stock by the method of inbreeding coefficients without any arithmetical computation on his part beyond the simple addition of a column of figures."

Analyses of fodder plants, grasses, ensilages, etc., J. C. BRUNNICH (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1912-13, pp. 72, 73*).—Complete analyses are given of the following feeding materials: Ditch millet (*Paspalum scrobiculatum*); cockshin grass (*Panicum crus-galli*); barley grass (*P. decompositum*); *P. divaricatissimum*; *P. flavidum*; *P. foliosum*; brown top (*Pollinia fulva*); scented golden beard (*Chrysopogon parviflorus*); Johnson grass (*Sorghum halepense*); *S. plumosum*; tall oat grass (*Anthistiria avenacea*); kangaroo grass (*A. ciliata*); *Agropyron scabrum*; *Stipa aristiglumis*; bamboo grass (*S. micrantha*); *Deyeuxia forsterii*; white top (*Danthonia pallida*); Rhodes grass (*Chloris gayana*); stink grass (*Eragrostis major*); arrow-root bagasse, silage; wheat, thistles, and wild mustard; pumpkin (cow, crown, and silver); green fodder (cape barley and cowpea); and Indian and seedling cane.

Report of commercial feed stuffs (*Louisiana Stas. Feed Stuffs Rpt. 1912-13, pp. 132*).—This bulletin reports analyses on 12,226 samples of the following feeding stuffs: Cotton-seed meal and feed, rice bran, rice polish, wheat bran, wheat middlings, corn chop, molasses feeds, hominy feeds, brewers' grains, alfalfa meal, blood meal, meat scrap, bone meal, tankage, dried beet pulp, and various mixed and proprietary feeds.

Feeding stuff analyses, edited by H. B. McDONNELL (*Md. Agr. Col. Quart., No. 62 (1913), pp. 11*).—Analyses are reported of the following feeding stuffs: Beef scrap, gluten feed, linseed meal, dried brewers' grains, meat meal, cotton-seed meal, molasses feeds, dried beet pulp, tankage, and various proprietary stock feeds.

Process of raising the nutritive value of brewery grains, and also of treating spent hops, malt dust, dust obtained in cleaning cereals and the like, and obtaining a feed for cattle, M. HAMBURG (*English Patents 29,996, Dec. 30, 1912; 14,808, June 26, 1913; abs. in Jour. Soc. Chem. Indus., 32 (1913), No. 22, p. 1081*).—A report of a patented process in which "ten parts of pressed and washed yeast are heated to from 50 to 60° C., and stirred until a liquid mass is obtained; this is mixed with 90 parts of wet grains, spent hops, malt dust, or the like, and the mixture is pressed and dried at a low temperature. The yeast may also be mixed with the grains, or with the other substances and a suitable quantity of water, before it is heated."

Yeast combination for use as a feed for animals, F. GOTHARD (*English Patent 2,848, Feb. 4, 1913; abs. in Jour. Soc. Chem. Indus., 32 (1913), No. 22, p. 1082*).—A patented process in which "cattle feed is prepared by drying and grinding a mixture of yeast, 50; peat moss, 25; and hop meal, 25 per cent."

Manufacture of a cattle feed, with simultaneous recovery of cellulose, resin, etc., from cellulose-containing materials, J. KÖNIG (*German Patent 265,483, Feb. 15, 1912; abs. in Jour. Soc. Chem. Indus., 32 (1913), No. 22, p. 1063*).—"Wood, especially the wood of conifers, is heated, if necessary under pressure, first with dilute alkalis, chiefly ammonia, and then with dilute mineral acid, or first with acid and then with alkali, as far as possible in stoichiometrical proportions. The residue is subjected to the usual bleaching process, and the spent liquors are evaporated, either separately or together, and with or without addition of other substances suitable for use as cattle feed."

Comparative experiments on the digestibility of rye and wheat and of the ground meal for sheep and swine, F. HONCAMP, P. NEUMANN, and H.

MULLNER (*Landw. Vers. Stat.*, 81 (1913), No. 3-6, pp. 205-288).—Experiments conducted in feeding wheat and rye products to sheep and swine resulted in the following estimated coefficients of digestibility:

Digestibility of wheat and rye products by sheep and swine.

Kind of feed.	Dry matter.		Organic matter.		Protein.		Fat.		Nitrogen-free extract.		Crude fiber.	
	Sheep.	Swine.	Sheep.	Swine.	Sheep.	Swine.	Sheep.	Swine.	Sheep.	Swine.	Sheep.	Swine.
	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>
Wheat sprouts.....	89.3	86.9	93.8	90.1	89.4	85.5	91.1	88.1	41.3
Rye sprouts.....	91.7	83.5	91.8	86.4	90.3	87.8	91.5	90.8	91.4	67.7
Rye coarse meal.....	88.5	90.8	90.3	91.5	78.1	85.2	52.2	47.3	94.5	94.0	11.1	19.7
Wheat coarse meal.....	85.0	89.9	87.0	90.1	84.0	85.6	77.8	72.0	92.6	93.3	33.3
Wheat screenings.....	63.8	70.5	66.8	74.4	75.4	75.5	77.9	92.5	65.5	77.4	60.8	13.7

It is estimated that the rye sprouts contained 21.23 per cent of digestible protein and 75.8 per cent starch; wheat sprouts 21.97 per cent digestible protein and 74.7 per cent starch. The percentage of weed seeds was also estimated and their germinating strength determined.

The general conclusions reached were that rye and wheat sprouts are protein-rich and highly digestible for both sheep and swine; and that the meals of rye and wheat vary in digestibility according to the degree of grinding, the coarser meals invariably being the more digestible.

Digestibility experiments with sheep.—Para rubber seed cake, S. J., M. AULD (*Jour. Agr. Sci. [England]*, 5 (1913), No. 4, pp. 429-433).—The product used in these experiments is the press cake left after expression of the oil from the kernels of the seed of the Para rubber tree. It was thought that the press cake might be dangerous for use as a cattle feed owing to the high content of prussic acid in the seed but the cake was found to be free of this acid. The composition of the cake is given as follows: Moisture 9.27, protein 29.84, ether extract 20.11, nitrogen-free extract 33.08, crude fiber 3.15, and ash 4.55 per cent.

The average coefficients of digestibility of the Para rubber seed cake as determined by several sheep-feeding experiments were as follows: Protein 90.09, ether extract 97.2, nitrogen-free extract 95.3, and crude fiber 100 per cent. These would make it one of the most digestible concentrated feeds available.

Feeding experiments with cattle and sheep, 1902-1913, D. A. GILCHRIST (*County Northumb. Ed. Com. Bul.* 20 (1913), pp. 46).—In this bulletin former experiments (E. S. R., 26, p. 767) are summarized and the experiments for 1911-1913 given in detail.

It is concluded that the results from feeding an equal amount of dry matter in yellow turnips and in swedes to store cattle during the winter months are very similar.

The advantage of box feeding of cattle over stall feeding was found to be considerable. Cattle wintered out of doors showed the best gains at the end of the winter period, but slightly lower gains during the spring and summer periods than those that had been wintered indoors.

Comparing swedes, yellow turnips, and no roots for fattening sheep the results were slightly in favor of swedes. Sheep fed outside made decidedly lower gains than those fed inside. Bullocks made somewhat greater gains than heifers, although heifers fed in box stalls made better gains than the bullocks in stalls. Results indicated practically no advantage from linseed cake

fed to cattle in addition to the normal ration, especially where this is sufficient and well balanced.

Rations for fattening cattle, store cattle, milch cows, and sheep, both including roots and without roots, are suggested.

Feeding experiments (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1913), No. 1, pp. 29, 30*).—Two lots of 9 steers each were fed 14 weeks on chopped straw, meadow hay, potatoes, rye bran, and cotton-seed meal, each lot receiving a starch value equivalent of 14 kg. per day. Lot 1 received 2.5 kg. of digestible protein, lot 2 1.8 kg. During this period lot 1 made an average daily gain of 0.86 kg. per head, and lot 2 0.83 kg.

Two lots each of fifteen 50 kg. pigs were fed 70 days on steamed potatoes, barley meal, and meat meal, both lots receiving the same starch value equivalent. Lot 1 received a digestible protein allowance ranging from 4.5 kg. to 3 kg. per day; lot 2, 3.5 to 2.5 kg. Lot 1 made an average daily gain of 0.58 kg. per head, lot 2 0.45 kg.

The importance of food accessories as shown by rat-feeding experiments, F. C. COOK (*Abs. in Science, n. ser., 38 (1913), No. 984, p. 675*).—"Most of the 12 white rats fed on a basal diet of protein, fat, carbohydrates, and salts for 80 days lost weight during the last 3 weeks. For 35 days immediately following, 5 cc. of meat extract, plant extract solution, or milk were alternately added to the basal diet, the nitrogen and sodium chlorids being equal. Milk and meat extract stimulated growth, plant extract showed little stimulating power. Eleven young white rats fed for 35 days on the basal diet, plus one of the 3 accessories, showed similar results. Milk, also meat extract, gave the biuret reaction and precipitates with phosphotungstic acid. Plant extract gave neither. Meat extract is a hydrolyzed product practically free from fat and carbohydrates. The rats gained more on a smaller number of calories when milk or meat extract was ingested than when fed on the basal diet alone."

Germany's meat supply, R. P. SKINNER (*Daily Cons. and Trade Rpts. [U. S.], 16 (1913), No. 297, pp. 1388, 1389*).—It is reported that there is a general increase in the cost of meat in Germany, with an accompanying decrease in number of animals slaughtered. The ravages of foot-and-mouth disease account in part for this condition.

Statistics are included giving the wholesale prices of cattle and meat for 1910-1913, the number of domestic animals in Germany, the number of slaughtered animals, and the number of cases of foot-and-mouth disease.

Utilization of entrails of cattle, sheep, and horses in slaughterhouse practice, A. LHOSTE (*Hyg. Viande et Lait, 7 (1913), No. 12, pp. 583-589*).—A description of French methods of cleaning, scouring, desiccating, sulphuring, and further preparation of cattle, sheep, and horse entrails for commercial use.

The cattle of Brazil, L. MISSON (*Vie Agr. et Rurale, 2 (1913), No. 50, pp. 625-633, figs. 6*).—A description of the native breeds of cattle of Brazil, with comments on the comparative value of crossing with the Holstein, Flemish, Limousine, and other European breeds. The Limousine has proved especially valuable in crossing for beef production and dual purpose cattle, while the Flemish and Holstein are apparently best suited for milk.

Organization for the breeding of Swiss spotted cattle, J. KÄPPELI and G. LÜTHY (*Ann. Agr. Suisse, 14 (1913), No. 3, pp. 219-253*).—This includes a history of the Swiss spotted red breed of cattle and comments on herd book organization and membership, distribution, and utility value of this breed, and of the exportations to other countries.

Crossing the cattle of Tunis and the zebu, ROEDERER (*Jour. Agr. Prat., n. ser., 26 (1913), No. 39, pp. 404-406*).—It is stated that the crossing of the zebu

and the cattle of Tunis has been practiced since 1865, with the result that the native has been rendered more resistant to disease, increased in size and weight, and improved in quality of flesh and in working capacity.

Utilization of feed in the zebu, C. Pucci (*Mod. Zootro, Parte Sci., No. 2* (1913), pp. 41-50, figs. 2).—Complete digestive trials were made with the zebu and the cattle of Todi, Italy. The digestibility of meadow hay was shown to be dry substance 53.56 per cent, protein 53.03, fat 44.83, nitrogen-free extract 55.86, fiber 57.38, and ash 24.61. The feeding of linseed meal with the hay increased the digestibility.

Plants used for food by sheep on the Mica Mountain summer range, R. K. Beattie (*Washington Sta. Bul. 113* (1913), pp. 3-21, pls. 8).—This bulletin reports a study made of the sheep food plants and other range conditions on the Mica Mountain Range of Washington and Idaho.

It was found that "in the region studied, shrubby plants and brush are much more important as sheep feed than are grasses and herbs. The principal feed plant of the yellow pine forest is the buckbrush. Its 2 species are by far the most fattening plants on the range. The principal feed plant of the white pine forest is the huckleberry. Under the conditions observed, the sheep never eat ferns and conifers. Well managed sheep grazing is having no deleterious effect on the reproduction of the forest or of its grazing plants. The presence of the sheepmen in the forest during the fire season is an assistance in fire protection. The leasing system for grazing lands tends to eliminate injurious competition, overgrazing, and grazing feuds, and is by far the most satisfactory method of handling these lands. Well managed sheep grazing, such as is here reported, is a valuable and important factor in the sheep business of the Northwest. Such grazing should be encouraged and extended till every square mile of available summer and winter range is in use and the wool and mutton used in the Northwest is produced in the Northwest."

A bibliography is appended.

[Sheep feeding experiments], C. I. Bray (*Oklahoma Sta. Rpt. 1913, pp. 33-36*).—In comparing an alfalfa and corn ration with silage and cotton-seed meal for breeding ewes it was found that while somewhat greater gains were made on the former ration, reasonable gains were made on the latter at a considerably lower cost. The lambs dropped by the ewes fed silage were as healthy and strong as from those fed alfalfa and corn.

In an experiment with fattening sheep, silage was compared with alfalfa as a roughage, using the same meal mixture in each case. The gains per head per day of the silage lot were 0.42 lb., of the alfalfa lot 0.545 lb.; the cost per pound of gain 6.6 and 7.5 cts.

Five lots of 4 pigs each were fed the following rations: Corn alone; corn and meat meal, 10:1; corn and cotton-seed meal, 8:1; corn and skim milk, equal parts by weight; and Kafir corn and meat meal, 10:1. The respective gains per head per day were: 0.375, 0.614, 0.71, 1.1, and 0.77 lbs.; the cost per pound of gain 7, 5.5, 4.6, 4.3, and 4.1 cts.; and the return from 1 bu. corn \$0.78, \$1.04, \$1.18, \$1.57, and \$1.25.

A summary is given of the results of wool investigation work for the years 1910-11 and 1912-13. This relates to the average number of fibers per square inch, the average breaking strength, percentage of elasticity, weight of fleece, value of fleece, and percentage of yolk in the Dorset, Merino, Shropshire, Shropshire-Dorset, and Dorset-Merino breeds and cross breeds.

Investigations on the digestibility of Sphagnum moss, peat molasses, etc., S. Goy (*Landw. Vers. Stat., 82* (1913), No. 1-2, pp. 1-92).—Experiments were conducted with sheep to determine the relative digestibility and food value of

turf-molasses feed, both unneutralized and with the acidity of the turf, which is due to the presence of humic acid, neutralized with sodium hydroxid.

It was found that the neutralized feed is as digestible, as palatable, and of better keeping quality than the nonneutralized. In a warm, damp room the nonneutralized feed underwent a chemical and physical change, becoming moldy and taking on a distinct aged smell. This was not the case with the neutralized feed material and under dry, cool conditions it retained its quality indefinitely.

Sphagnum turf was found to be most digestible when fed in small allowances, and the feeding of an increasing quantity of the turf lowered the digestibility of the other materials fed with it. The energy content of the digestible portion of the turf was relatively higher than that of the indigestible portion. Each animal was found to possess an individual degree of digestibility for turf.

A study of the digestibility of the refuse from sulphite-cellulose manufacturing showed that the nutrients of this feed are relatively unavailable and that it decreased the digestibility of other materials fed in conjunction with it.

Caracul sheep, T. R. GARCÍA (*Bol. Min. Agr. [Buenos Aires]*, 14 (1912), No. 10, pp. 1145-1178, figs. 23).—An account of the history, utility value, body characteristics, and introduction into Argentina of this breed of sheep. The adaptability of the caracul sheep to Argentine conditions is pointed out and its exploitation advocated. It is thought that the introduction of this breed will mean a new era in the history of sheep production in that country.

Notes on the camel, B. DANOU (*Bul. Off. Gouv. Gén. Algérie*, No. 23, Sup. (1913), pp. 145-157).—An account of the breeds and types of camels of Algeria, their care and management, and the diseases to which they are subject. The production of camel hair as a commercial product is also discussed.

Hog feeding, G. C. WHEELER, T. R. H. WRIGHT, ET AL. (*Kansas Sta. Bul.* 192 (1913), pp. 355-427, figs. 8).—Summarizing the results of experiments conducted during 1904-1911 to determine the value of corn alone and with various supplements as fattening rations for hogs the following table is given:

Averages of various tests of supplements to corn meal for hogs.

Ration.	Number of hogs.	Average number of days fed.	Average daily gain per hog.	Feed required to make 1 lb. of gain.	Cost of feed required to make 1 lb. gain.
			Pounds.	Pounds.	Cents.
Corn alone in dry lot.....	72	79.88	0.914	6.25	5.94
Corn and alfalfa hay in dry lot.....	59	86.70	1.110	6.27	5.57
Corn and meat meal or tankage in dry lot.....	162	54.00	1.580	4.72	5.27
Corn, shorts, and meat meal or tankage, in dry lot...	144	52.68	1.700	4.58	5.05

It is estimated that with pork at 6 cts. per pound the value returned per bushel for corn in tests where corn alone was fed averaged 53.6 cts.; where corn and alfalfa meal were fed 57.6 cts.; corn and meat meal or tankage 65 cts.; and corn, shorts, and tankage or meat meal 69.8 cts. These experiments indicate the increased value of corn for pork production from the use of highly nitrogenous supplementary feeds.

In an experiment comparing the economy of gains between large and medium type Poland China hogs, the former made the most economical gains, while the latter finished more quickly and carried a finish that would command a higher price on the market. In another experiment it was found that if corn is taken

as the basis of comparison, milo maize, Kafir corn, and sorghum seed each have a higher feeding value when fed with protein supplements, such as shorts and tankage, than when fed with alfalfa hay; that for fattening hogs, milo maize and Kafir corn each have a feeding value slightly lower than corn; and that sorghum seed, while lacking in palatability, has considerable feeding value.

"A comparison of wet and dry mixtures of corn, shorts, and meat meal showed an average daily gain per hog of 1.95 lbs. on the dry ration and 2.31 lbs. on the wet ration."

"An average of 3 lots receiving different brands of condimental stock feed with corn, in comparison with a lot on corn meal, shorts, and meat meal, showed an average daily gain of 0.76 lb. with stock feed rations and 1.69 lbs. daily gain on the corn, shorts, and meat meal ration."

"Hogs fattened on alfalfa and rape pastures made cheaper and more rapid gains than hogs fattened in dry lots. Hogs fattened on rape pasture made gains as cheaply as those fattened on alfalfa pasture. . . .

"When spring shoats were full fed through the summer on alfalfa or rape pasture and finished in the fall in dry lots, those fed a grain ration of corn, shorts, and tankage finished 45 days sooner, averaged 48 lbs. a hog heavier, made gains at a cost of 15 to 20 cts. a hundred pounds less, and sold on the market for from 10 to 20 cts. a hundred pounds more than those fed on corn or corn and alfalfa hay.

"When spring shoats were grown with a limited amount of grain on alfalfa pasture during the summer and finished in dry lots in the fall and early winter, those finished on corn, shorts, and tankage were ready for market 15 days earlier, weighed 55 lbs. a hog more, required 15 cts. less to produce each 100 lbs. of gain, and sold for 20 cts. a hundred pounds more than those finished on corn or corn and hay.

"Spring shoats that were full fed through the summer and thus pushed for an early market, not considering interest and risk, made gains at an average cost of from 15 to 20 cts. a hundred more than similar shoats grown through the summer on pasture and a small amount of grain and finished in the fall and winter in dry lots."

A metabolism experiment with swine, E. B. FORBES (*Abs. in Science, n. ser., 38 (1913), No. 984, pp. 678, 679*).—It is stated that "the usual practical rations for swine contain an excess of acid over basic mineral elements. Urinary ammonia varies directly with this excess of mineral acid, provided the protein intake remains the same. Increased protein intake increases urinary ammonia. This excess of mineral acid in practical swine rations seems not to affect calcium retention.

"Water drinking caused the elimination of sodium and chlorin; abstinence from drinking leads to the retention. The feces may contain an abundance of sodium, but are nearly free from chlorin. Potassium, magnesium, and chlorin balances were usually positive, but were negative during periods of maximum intake, apparently through overresponse in the way of protective elimination of excess ingested.

"Calcium retention was satisfactory only on rations containing meat meal containing considerable bone and skim milk. Neither cereals nor soy beans furnish the calcium requisite for growth. An excess of magnesium to calcium caused loss of calcium with a ration of rice polish and wheat bran. The excess of magnesium to calcium in corn and in other practical rations does not appreciably restrict calcium retention.

"The important deficiencies of corn are, in order of magnitude, first, calcium; second, phosphorus; third, nitrogen.

"Creatin elimination was entirely independent of food, but varied in the same order as live weight, weight of dressed carcass, of flesh, of bones, and of blood.

"Soy beans, meat meal, and skim milk increase the digestibility of the carbohydrates of the corn with which they are fed. Meat meal and skim milk increase the apparent digestibility of the fat, and decrease the apparent digestibility of the crude fiber of the corn with which they are fed, the results being digestion coefficients of more than 100 and less than nothing."

Feeding of lecithin, C. PUCCI (*Atti. R. Acad. Econ. Agr. Georg. Firenze*, 5. ser., 10 (1913), No. 4, pp. 425-451, figs. 3).—Three experiments, in which lecithin was fed in varying quantities to pigs, showed that this phosphorus-containing feed had no influence on increase in weight.

Calcium feeding, J. PAECHTNER (*Wehnschr. Brau.*, 30 (1913), No. 37, pp. 491-494).—It is estimated that in feeding a 700 kg. work horse a ration composed of roughage (3 kg. meadow hay and 4 kg. of chopped straw) and 7.5 kg. corn, 14 gm. of CaO should be added in the form of chalk or commercial preparation. If 8.5 kg. dried potatoes is substituted for the corn, 10 gm. CaO is suggested.

Color inheritance in the horse, E. N. WENTWORTH (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 11 (1913), No. 1-2, pp. 10-17).—The author states that there has been a tendency among investigators to arrange all colors as an epistatic and hypostatic series, expecting them, then, to conform to the simple laws of presence and absence. He attempts to show the fallacy of this.

A microscopic examination and simple chemical tests reveal only 2 pigments in the coat of the ordinary horse, these corresponding to the red or yellow and the black pigments found in rodents. The various factors influencing color are discussed and the different colors qualitatively grouped. The tentative composition as regards the different factors is given for the different colors.

There is appended a short bibliography of works on this subject.

[Trotting horses of Russia] (*Horse Rev.*, 48 (1913), No. 24, pp. 1488, 1489, figs. 9).—The trotting horses of Russia are of 2 classes; the pure-bred Orloffs, a breed established 2 centuries ago, and the "metis" or mixed-bred ones, which have been produced by mingling the native Orloff blood with that of foreign strains, almost exclusively American. While the "metis" horses are as a rule distinctly superior to the pure Orloffs, the latter are in popular favor.

[Poultry breeding], G. WIENINGER (*Monatsh. Landw.*, 6 (1913), No. 11, pp. 339-344).—In poultry-breeding trials to determine the relative value of eggs of different weights it was found that the shell comprised 13.4 per cent of eggs weighing 40 gm., and 10.1 per cent of eggs weighing 70 gm. The respective protein contents were 12.29 and 12.76 per cent; the fat contents 10.13 and 10.51 per cent; the phosphoric acid 0.433 and 0.449 per cent; and the lime 4.85 and 5.03 per cent.

[Cotton-seed meal v. beef scrap for chicks], H. J. WHEELER (*Rhode Island Sta. Rpt.* 1912, pp. 202, 203).—In this experiment 4-weeks-old chicks were fed for 15 weeks on the same amount of a uniform basal ration, protein being added in the form of cotton-seed meal or beef scraps. The results indicated that very little difference exists in the value of the protein in the 2 concentrates, either in the weight of the chicks or in the nitrogen recovered in the cooked portion. It is noted that as a rule, chicks will, if allowed, consume more beef scraps than cotton-seed meal, and in consequence make a larger growth.

Poultry on the farm, L. L. JONES (*Bul. Ga. State Col. Agr.*, 2 (1913), No. 2, pp. 13-44, figs. 10).—This bulletin treats in a popular way of poultry house

construction; feed, care, and management of poultry on the farm; hatching and rearing chickens; and other related subjects.

Unique method of hatching eggs, C. F. BRISSEL (*Daily Cons. and Trade Rpts.* [U. S.], 16 (1913), No. 295, p. 1355).—A brief sketch of the Chinese incubator method of hatching eggs, which consists in covering alternate layers of eggs with rice and heating once in 24 hours, the eggs being taken out at such times.

The international poultry book, G. WOODWARD (*Ballarat, Australia*, [1913], pp. 282, pl. 1, figs. 40).—This book treats in detail of the breed characteristics and fancy points involved in the various standard breeds of poultry, ducks, and geese. There are included short discussions on various problems of breeding, feeding, care, and management of poultry.

DAIRY FARMING—DAIRYING.

Holstein-Friesian color markings, M. H. GARDNER (*Hoard's Dairyman*, 46 (1914), No. 23, pp. 690, 691).—The author explains the color marking requirements of the Holstein-Friesian Association in detail. The occasional birth of a red and white animal from pure-bred stock is explained as a reversion in color markings to some more or less remote red and white ancestor.

Registration rules for cows in Denmark, J. J. DUNNE (*Hoard's Dairyman*, 46 (1914), No. 23, p. 684, fig. 1).—The average measurements of animals accepted for registration in the Funen Herd Book, Denmark, are as follows: Height approximately 50½ in., depth of chest 27½, circumference of chest 84½, length of body 56½, width of hip bones 21½, and width of hip joints 18½ in.

Brown Swiss registry of production reports, F. FREEMYER (*Hoard's Dairyman*, 46 (1914), No. 24, p. 735).—It is reported that of the 94 cows and heifers accepted for registry, 1 cow has a record of 19,460.6 lbs., 3 cows have records above 16,000, 7 above 15,000, 22 above 12,000, and 53 above 10,000 lbs. of milk; and 1 cow has produced 708.16, 4 cows above 600, 21 above 500, and 51 above 400 lbs. of milk fat.

[Champion Ayrshire cow], V. E. FULLER (*Pract. Dairyman*, 6 (1913), No. 24, pp. 1178, 1179, 1183, 1185, 1189, 1190, fig. 1).—An account of the history, management, and feeding of the world's champion Ayrshire cow, Auchenbrain Brown Kate IV, whose record is 23,022 lbs. of milk and 1,078 lbs. of 85 per cent butter.

Tests of the performance of goats belonging to the goat-breeding associations of Brügggen, Harsum, Schüttorf, and Wessenstedt, Hanover, VIETH (*Ztschr. Ziegenzucht*, 1913, Nos. 9, pp. 130-133; 10, pp. 149-151; 13, pp. 200-203; 14, pp. 213-217; abs. in. *Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Discases*, 4 (1913), No. 9, pp. 1394-1396).—In these tests the Harz breed of goats showed higher yields than the Saane breed. The average milk yield of goats milked 3 times a day was morning 3.2, noon 1.82, evening 2.16 lbs.; and the average fat content 3.22, 4.28, and 3.64 per cent, respectively. Little difference was found between the milk yield of younger and older goats. The tests showed that the capacity of goats for milk production is an individual property and that there is no determined relation between the amount of milk produced and its fat content.

Studies in milk records: On the accuracy of estimating a cow's milking capability by her first lactation yield, W. GAVIN (*Jour. Agr. Sci. [England]*, 5 (1913), No. 4, pp. 370-390, figs. 5).—The results of these studies were based upon the records of 336 cows which have had 5 or more calves. The "revised maximum" (the highest figure common to the 3 highest day yields of a lactation) was used as a measure of yield.

It was found that "the first lactation shows greater variability than the second, third, fourth, or fifth. The estimation of one lactation from another can not be made with great accuracy, since the correlation coefficient between even successive lactations does not rise above $+0.6$ With cows giving a fairly high or fairly low first lactation revised maximum, this figure should be used to determine whether they shall be kept or not; but with cows giving a medium first lactation revised maximum, of 10 to 11 quarts, it is worth waiting to obtain the increased accuracy of an estimate based on the mean of first and second lactation revised maximum."

Tables are given for estimating maximum lactation from both the first lactation and the mean of the first and second.

Trial of milking machine, A. CUGNINI (*Indus. Latt. e Zootec.*, 11 (1913), Nos. 8, pp. 115, 116; 9, p. 132; 10, pp. 152, 153, figs. 3; 11, pp. 168, 169; 12, p. 185; 13-14, pp. 200-203).—The principal conclusions drawn from trials with a milking machine were that machine milking, supplemented by hand stripping, had no appreciable depressing influence on either the quantity or quality of the milk. It was slower than hand milking, the expenses incurred were no lower, and to preserve hygienic conditions scrupulous cleanliness in the apparatus was necessary.

Relation of condition of feed to milk production and hygienic value of milk, J. E. LUCAS (*Indus. Lait. [Paris]*, 38 (1913), No. 47, pp. 753-761).—This reports experiments in which sugar beets in different stages of fermentation and of preparation were fed to milch cows to determine their feeding value and also the effect on the development of micro-organisms.

It is concluded from these experiments that the form in which the beets are fed has but little influence on the hygienic value of the milk, that the feeding of dried beet pulp has no advantage in milk-fat production over that fed wet or damp, and that the feeding of whole beets shows only a slight advantage over chopped beets.

Oats and flavor of milk (*Amer. Cult.*, 76 (1914), No. 2, p. 4).—Results from experiments by the Dairy Division of the U. S. Department of Agriculture with 6 cows, 3 fed a grain ration of corn meal, bran, and cotton-seed meal, and 3 fed oats and cotton-seed meal 5:1 are cited, which indicated that contrary to common opinion crushed oats in no way improves the flavor of the milk.

Relation between the bacterial flora of milk and of pasture, A. WOLFF (*Centbl. Bakt., [etc.]*, 2. Abt., 39 (1913), No. 15-17, pp. 411-419).—In studying the influence of the food material on the fungi and bacterial flora of milk, it was found that *Bacterium coli*, *B. aërogenes*, *Micrococcus pallidus*, and *Sarcina liquefaciens* were common to cultures of both the milk and of the pasture crop. In one test *Bacillus mycoides* and *Bacterium erythrogenes* were common to both cultures, while in other cases they were found in but one of the cultures.

The influence of soil on the curdling of milk (*Milchw. Zentbl.*, 42 (1913), No. 17, p. 542).—The investigations showed that there was a variation in the readiness of the forming of curd in different sections, both as to the time required and in the consistency of the curd. This is explained as being due to the type of soil. Milk produced by cows pastured on swampy soil gave a greater amount of curd and the curdling was slower; that from a heavy clay soil resulted in a medium curd with slow coagulation. Pasturing on a porous loam resulted in a medium curd, especially if the loam was moist and had a gravel subsoil, and where dry the curd was tough. Milk produced on limy soil required little rennet and resulted in tough curd.

Effect of foot-and-mouth disease upon composition of milk, J. HONIGMUND (*Molk. Ztg. Berlin*, 23 (1913), No. 52, pp. 619, 620).—In these studies it was found that no change occurred in the specific gravity or the quantity of

dry substance, while the protein content underwent but slight change. The fat and ash contents of the milk were increased, and the sugar content was lower.

Tuberculosis and milk, R. VON OSTERTAG (*Ztschr. Fleisch u. Milchhyg.*, 24 (1913), Nos. 3, pp. 49-53; 4, pp. 75-80; 5, pp. 99-104; 6, pp. 122-129).—This is a general résumé of investigations relating to tuberculosis and milk, and includes a bibliography of 80 references on this subject.

On the possibility of increasing the fat content of milk, GRUMME (*Ztschr. Expt. Path. u. Ther.*, 14 (1913), No. 3, pp. 549-554).—In three 4-day experiments in which goats were fed malt-tropon, in addition to the ordinary feed, there resulted an average increase in milk yield of 18 per cent, in fat content of about 32 per cent, and in yield of butter of about 55 per cent.

The fuel value of milk in relation to its price and its nutritive value, G. FASCETTI (*Indus. Latt. e Zootec.*, 11 (1913), No. 12, pp. 183, 184).—The author believes that the fuel value of milk is proportional to its nutritive value and should be taken as the basis for its trade value. He suggests simple formulas for calculating the fuel value from determinations of the specific gravity and fat content.

Variations in storeroom and fresh milk, S. GUERRERA (*Mod. Zootatro, Parte Sci.*, No. 11 (1913), pp. 455-460).—It is noted that the *Bacillus coli* group develop in from 18 to 20 hours, staphylococci in 46 to 50, racidiform bacteria in 40 to 50, *B. lactis* in 14 to 16, and a general mixture of bacilli in from 30 to 36 hours.

It is concluded that the keeping of milk depends largely upon the type or variety of bacilli present in the milk.

Report of the dairy and cold storage commissioner, J. A. RUDDICK ET AL. (*Rpt. Dairy and Cold Storage Comr. Canada, 1913*, pp. 1-7, 50, 51, 94-123, 128-133).—Although a large increase in the total quantity of milk produced in Canada, and a very noticeable development in some parts of the prairie Provinces, is reported, there has been a material increase in the butter imports during the past few years, mainly from New Zealand.

Reports of cow testing associations and of dairy record centers are given, showing the progress made and the increases in yields as the results of these associations. Statistics are also given on prices, and the exports and imports of cheese and butter from different countries.

The progress of dairying in Canada, J. A. RUDDICK (*Separate from Rpt. Select Standing Com. Agr. and Colon. [Canada], 1912-13, App. 5, pp. 117-131*).—A material decrease in butter and cheese exports from Canada to Great Britain is reported, although the annual production of creamery butter in Canada has doubled since 1900. The annual imports of butter from the United States to Canada are given as 1,468,562 lbs., mostly into British Columbia from Oregon, Washington, and California. A decrease in cheese production is attributed to an increased city milk consumption and the development of the condensed milk industry.

The progress of the Irish dairying industry, A. P. WILSON (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 4, pp. 677-697).—In this paper the author outlines the improvements made in educational facilities, gives statistics relating to the output of dairy products, and presents data on the cost of manufacturing butter and prices received.

Chinese imports of dairy products, G. E. ANDERSON (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 5, p. 76).—It is stated that while American butter was formerly sold in considerable quantities along the China coast it has been supplanted by the cheaper Australian product, which now constitutes about two-thirds of the imports of high-grade goods. Cheese is the only dairy prod-

uct of the United States that is competing successfully with dairy products of other countries in these markets. The use of oleomargarine and other artificial butters is increasing, but the United States has no part in the trade.

A study on milk and cheeses in Greece, with regard to their chemical composition, P. G. PALLATSEAS (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 9, pp. 1335-1341).—The principal sources of milk supply in Greece are sheep and goats. It is reported that the sheep on the island of Scopello drop 2 and often 4 lambs. The milk yield often reaches 2 to 5 pts. per day, especially the first 3 months after lambing.

There are about 3,000,000 goats in Greece. The indigenous mountain breed gives but little milk, while Maltese goats give from 3 to 5 pts. per day.

Analyses of milk from sheep and goats are reported, and summarized as follows:

Average chemical composition of sheep and goat milk.

Source of milk.	Specific gravity.	Total solids.	Protein.	Fat.	Sugar.	Ash.
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Flock of 400 Vlachica ewes.....	1.0358	18.45	6.24	7.11	4.19	0.92
Herd of 300 mountain goats.....	1.0305	15.22	4.20	6.11	4.12	0.80
Maltese goats.....	1.0303	13.79	3.80	4.91	4.27	0.81

The cheeses of Greece are of 2 classes, hard and soft, and made from ewe's and goat's milk. Analyses of the principal cheeses are reported.

Gouda cheese, W. D. KOOPER (*Molk. Ztg. [Hildesheim]*, 27 (1913), No. 92, pp. 1783, 1784).—Analyses of 57 samples of cheese made from milk ranging from 2.51 to 4.22 per cent in fat content showed that while in general the fat content of cheese increases with a corresponding increase in that of the milk, this is not always the case. There was a similar increase in the fat content of the whey.

It was found in general, other factors being equal, that cheese from evening milk is richer than that from morning milk. Breed and the age of the cow had no influence on the fat content of the cheese.

Export of Italian cheese (*Indus. Latt. e Zootec.*, 11 (1913), No. 22, pp. 339, 340).—It is shown that the largest exports of Italian cheese are being made to the United States, Austria-Hungary, Argentina, and Great Britain. Statistics of exports for 1911-1913 are included.

Soft cheese making, MISS G. NEST-DAVIES (*New Zeal. Dept. Agr., Indus., and Com. Bul.* 29, n. ser. (1913), pp. 18, figs. 6).—This includes directions for the making of the cream, Gervais, Welch, Wensleydale, Coulommier, and club varieties of soft cheeses.

Report of the department of dairy husbandry, O. F. HUNZIKER (*Indiana Sta. Rpt.* 1913, pp. 38-44).—In a preliminary comparison of the efficiency of different methods of pasteurizing gathered cream for butter making, it is concluded that "flash pasteurization at 170 to 180° F. had the greatest germ-killing efficiency of any process tried in our experiments. During the winter months more resistant micro-organisms are present and higher temperatures are necessary for effective pasteurization than during the summer months. Yeast and molds, owing to their great resistance to heat, cold, and brine may be important factors in the deterioration of butter in storage. They are not destroyed by ordinary pasteurizing temperatures. Cream contains enzymes which may be a factor in the deterioration of storage butter. Most of these are rendered inactive but not all of them are destroyed by pasteurization at

165 to 175°. The olein is a highly unstable fat, susceptible especially to the action of heat and acid. Its oxidation spoils the flavor and keeping quality of butter. Early summer cream contains excessive olein, and unless reasonably sweet should not be pasteurized at high temperature. Butter from pasteurized cream contains less curd and the curd is in less soluble form than that from raw cream. Pasteurization of sour cream at high temperatures causes excessive loss of fat in the buttermilk, the fat being locked up in the curd content of the buttermilk. Other conditions being the same, pasteurized cream butter contains less moisture than raw cream butter; experimental results show an average difference of 1.5 to 2 per cent."

In determining the effect on the clearness and accuracy of the Babcock test of milk of the addition of corrosive sublimate, formaldehyde, potassium bichromate, and sodium salicylate in different amounts and held for 12, 7, and 14 days at 50 and 90°, it was found that "none of the samples containing preservatives varied in percentage of fat from those to which no preservatives had been added." Samples drawn immediately after calving and containing colostrum milk as well as milk immediately prior to drying up showed no appreciable difference in the accuracy of the test and the clearness of the fat. Where glymol was used the results were uniformly 0.2 per cent too low, indicating that in the reading of the test it is necessary to include the meniscus, in order to compensate for the residual fat lost in the bulb of the bottle.

Experiments showed no difference in the results obtained between the 10 per cent and 8 per cent milk test bottles. It was found that the time required for a test may be shortened somewhat by adding the first water before whirling without interfering in any way with the clearness and accuracy of the test.

An effort was made to utilize buttermilk by the manufacture of buttermilk powder. In this experiment 100 lbs. of buttermilk yielded about 9 lbs. buttermilk powder. The powder had a clean acid taste and was much relished. When fed to chickens it was eagerly consumed and produced satisfactory gains in weight. It was best diluted with about 10 parts by weight of water and mixed with the grain feed into a mush. However, it was found that the cost of manufacturing was somewhat out of proportion to the value of the product.

A method for determining the solids in evaporated milk is noted on page 509.

A preliminary comparison of bran and oats for milk production indicates that these feeds are of nearly the same efficiency when fed in a ration containing equal parts of bran or oats and corn meal, corn silage, and clover hay. Each pound of butter fat that was produced by the cows receiving the ration containing the bran cost 20.64 cts., while that from the cows receiving the oats cost 21.77 cts.

Licenses for creameries and testers, laws, rules, and regulations, O. F. HUNZIKER (*Indiana Sta. Circ. 41 (1913), pp. 16, fig. 1*).—This circular gives a text of the 1913 laws of Indiana, referring to the licensing of creameries and testers, together with the rules and regulations concerning the enforcement of these laws by the station, and information pertaining thereto.

VETERINARY MEDICINE.

Annual report of the veterinary pathological laboratory, Nairobi, R. E. MONTGOMERY (*Dept. Agr. Brit. East Africa Ann. Rpt., 1911-12, pp. 33-58*).—This, the author's third report, includes a discussion of work on diseases of cattle, equines, sheep, pigs, dogs, poultry, and game during the year ended March 31, 1912.

Annual report of the civil veterinary department, Bihar and Orissa, for the year 1912-13, D. QUINLAN (*Ann. Rpt. Civ. Vet. Dept. Bihar and Orissa,*

1912-13, pp. 9+VIII+6).—This, the usual annual report, deals with veterinary instruction, treatment of disease, preventive inoculation, breeding operations, etc.

Observations in regard to the feeding value and other properties of some plants in the Government of Viatka, M. PAPIKOW (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.)*, 4 (1911), No. 11, pp. 552-562).—A statement in regard to the value of certain plants as a feed for animals, especially from the standpoint of toxicity.

Analyses of some Wyoming larkspurs, I. F. W. HEYL, F. E. HEPNER, and S. K. LOY (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 7, pp. 880-885).—In this paper are given the results of proximate analyses of the leaves, pods, and roots of *Delphinium geyeri*, *D. glaucum*, and *D. nelsonii*. The roots of the latter have previously been found to contain a crystallizable alkaloid melting at 184 to 185° C. and to which the formula $C_{23}H_{33}NO_7$ had been assigned.

As the result of an examination of the leaves, which have been subjected to a most complete proximate analysis, it would seem that the leaves of *D. geyeri* are the most toxic of the 3 species because of their high crude alkaloid content. This alkaloid will, however, be studied further in order to note whether the alkaloids from the different larkspurs behave alike pharmacodynamically. "In order to gain some idea as to the toxicity of the crude alkaloidal mixture obtained from the leaves of *D. geyeri*, an intraperitoneal injection of 0.0564 gm. of the alkaloid as sulphate was made upon a guinea pig weighing 675 gm. Death followed in 9 minutes. In another experiment an intraperitoneal injection of 0.02 gm. as sulphate killed a guinea pig weighing 623 gm. in 35 minutes."

As *D. geyeri* is the most abundant species in Wyoming, it will be subjected to a complete chemical examination of all its constituents.

An analysis of the ash of the leaves of *D. geyeri* is included.

Poisoning of two cattle by tobacco juice, G. GIOVANELLI (*Schweiz. Arch. Tierheilk.*, 55 (1913), No. 4, pp. 178-182; *abs. in Vet. Rec.*, 26 (1913), No. 1328, p. 387).—The author reports observations in which cattle washed with a solution of tobacco juice to destroy lice were affected and the death of two heifers resulted.

Concerning sarcosporidin, L. COMINOTTI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 69 (1913), No. 4, pp. 264-271).—The author finds that the sheep sarcosporid (*Sarcocystis tenella*) contains a substance (sarcosporidin) which exerts a toxic action upon rabbits and sparrows characterized by paralytic symptoms. The minimum lethal dose of the dry substance for the rabbit is 0.0001 gm. It is possible in guinea pigs that are resistant to the toxic action of the sarcosporidin to produce anaphylactic shock through repeated injections, as well as to immunize actively rabbits through the injection of increased doses of the sarcosporid dry substance. An immune serum may be obtained from the goat through the administration of a series of intravenous injections of the dry substance, but the action of this immune serum is of short duration.

References to the literature are appended.

Researches on the Sarcosporidia, A. ALEXEIEFF (*Arch. Zool. Expt.*, 51 (1913), No. 5, pp. 521-569, pls. 3; *abs. in Bul. Inst. Pasteur*, 11 (1913), No. 18, pp. 786, 787).—This first part relates to the morphology of sarcosporids.

A consideration of the infective granule in the life history of protist organisms, H. HENRY (*Jour. Path. and Bact.*, 18 (1913), No. 2, pp. 250-258).—This discussion includes a general review of the literature on the subject, a list of 27 references being appended.

Investigations of the protozoa occurring in ruminants' stomachs, R. BRAUNE (*Arch. Protistenk.*, 32 (1913), No. 1, pp. 111-170, pls. 4).—The protozoa considered include two species of Lobosa (Amœbidæ), five species of Flagellata

of which three are described as new, and five species of Ciliata. A bibliography of 69 titles is appended.

A note on the transmission of spirochetes, J. L. TODD (*Proc. Soc. Expt. Biol. and Med.*, 10 (1913), No. 4, pp. 134, 135).—The author finds that the coxal fluid of *Ornithodoros moubata* infected with *Spirochæta duttoni*, even when free from anal excretion, contains spirochetes.

About the isolated active substances of the hypophysis, H. FÜHNER (*Deut. Med. Wchnschr.*, 39 (1913), No. 11, pp. 491-493, pl. 1).—From the pituitary body a pure crystalline material (composed of 4 substances) was isolated, which is capable of reducing and increasing the blood pressure and stimulating the contraction of the uterus. The name "Hypophysin" has been given to the substance which has all the properties of pituitary body extracts.

Deviation of complement with melitensis and paramelitensis, L. NÈGRE and M. RAYNAUD (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 20, pp. 1175, 1176).—While the serum of an animal immunized against *Micrococcus melitensis* will deviate with a paramelitensis antigen, it will deviate to a greater extent with the homologous antigen. On the other hand the paramelitensis serum deviates the same amount of complement with melitensis antigen as it does with paramelitensis antigen, consequently the complement fixation test can not be relied upon as a method for diagnosing Malta fever.

Specific therapy of contagious vaginal catarrh with local immunizing substances, K. v. SANDE (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 20, pp. 365, 366).—A description of colpitol, or an immunizing substance prepared from the streptococcus causing colpitis granulosa, and claimed to have given satisfactory results (*E. S. R.*, 27, p. 886).

The present status of foot-and-mouth disease in Germany, O. KNISPEN (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 52, pp. 699-701).—This discussion includes a table which shows the occurrence of foot-and-mouth disease in the 29 Provinces of Germany and in other European countries during the first 11 months of 1913.

Immunization tests with glanders vaccine, J. R. MOHLER and A. EICHORN (*Amer. Jour. Vet. Med.*, 8 (1913), No. 12, pp. 641-649; *Amer. Vet. Rev.*, 44 (1913), No. 1, pp. 31-46).—This investigation was made with guinea pigs and horses and a vaccine prepared by the New York City Board of Health laboratory which consists of a suspension containing 2 mg. of dried glanders bacilli to the centimeter. The horses, 17 in number, were purchased in the open market; they were aged but otherwise in fair condition and were subjected to the agglutination, complement fixation, and ophthalmic mallein tests previous to vaccination. The animals were kept in corrals and after vaccination were exposed to 2 animals which were artificially infected with the glanders organism. All of the animals were subjected periodically to a clinical examination.

In order to note whether any of the vaccinated animals were infected with the latent form of the disease, they were tested by the ophthalmic method. The method gave surprising results inasmuch as 2 of the vaccinated horses yielded a marked reaction. The glandered horses to which the animals were exposed also reacted strongly, as did also one of 2 check animals held in the corral for control purposes. One month later the animals reacted again but not quite so intensely. The 2 vaccinated horses and the check horse, when killed some months later, were found to have pulmonary glanders.

During the process of immunization the blood of all the horses was submitted to the agglutination and complement fixation tests. "It was found that the agglutination value of the serum of the vaccinated horses, as a rule, increased from the third day after the first vaccination and continued to rise for

a time. A decrease was again noted from 2 to 4 weeks after the last vaccination and appeared practically normal after 6 weeks to 2 months. A complement fixation with the sera of the vaccinated horses was obtained from the seventh to the ninth day after the first vaccination and they continued to give positive fixations from 2 to 3 months after the last vaccination. These serological results appeared only in the animals which gave no reaction to the ophthalmic test, while the blood of those vaccinated horses which gave a positive reaction to the eye test continued to give a positive fixation until they had been destroyed and proved to be affected with the disease. The same condition was observed in the animals which had been artificially infected with glanders.

"The serological results from these investigations appear to have a great significance with reference to the immunity produced by the injection of dead glanders bacilli. The fact that the demonstration of the presence of immune bodies in the vaccination horses ceased entirely in 2 or 3 months from the last vaccinated would indicate that after the lapse of such a time the animals have very little or no immunity against the disease. This is further substantiated also by the agglutination value of the sera returning to the normal level. . . .

"The results obtained by these investigations appear to be sufficient to demonstrate the unsatisfactory results of this method of immunization. Of the immunized animals, 3 contracted the disease from natural exposure, which is a large proportion when it is considered that all animals were aged and kept most of the time during the exposure out of doors. On the other hand, the fact that of the 2 check animals only one contracted the disease is additional evidence of the moderate character of the exposure, which further suggests the ineffectiveness of the immunization. In artificial infections of the vaccinated animals they showed no resistance whatsoever, as both vaccinated horses promptly developed an acute form of the disease from touching the Schneiderian membrane with a platinum loop, which has been touched to a growth of glanders bacilli. Thus for the present it seems advisable to abstain from immunizing horses by this method, as a practice of this kind may do more harm than good. Owners having horses which are supposedly immunized would naturally become careless, thinking their animals were resistant to the disease, and thus even a better opportunity would be offered for the propagation of the disease than if the horses were not vaccinated. Furthermore, the fact that the blood of vaccinated animals can not be utilized for serum tests for 2 or 3 months after the injections is also a great disadvantage in the eradication of the disease.

"As a result of this preliminary work it appears that the control and eradication of glanders must still be dependent upon the concentration of our efforts in eliminating infected horses and the adoption of proper precautions against the introduction of infected animals into stables free from the disease."

About the curative action of mallein in continuous but not specific secretion of the nose, ISNARD (*Abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 24, p. 433).—After giving one or two injections of mallein subcutaneously to subjects, the flow stopped in about one month postinjection.

Some bacteriological and environmental factors in the pneumonias of lower animals with special reference to the guinea pig, T. SMITH (*Jour. Med. Research*, 29 (1913), No. 2, pp. 291-323, pls. 3, figs. 2).—"The guinea pig is the host of 2 pneumonia-producing bacteria: (a) A minute motile bacillus, originally (but imperfectly) described by Tartakowsky, rediscovered and independently named by 3 workers subsequently, and redescribed in 1910 by M'Gowan as the cause of canine distemper (*Bacillus bronchisepticus*). It was encountered by Mallory in his studies on pertussis. It has been under observa-

tion by the writer since 1899; and (b) *Diplococcus pneumonia* or pneumococcus which also produces adhesive pleuritis, pericarditis, suppurative peritonitis, and general septicemia. In the author's studies, the pneumococcus infection was usually grafted on the pneumonia due to the motile bacillus. A study of the work of earlier observers indicates that both organisms have manifested gross differences in virulence in different epidemics.

"Independent of and frequently associated with pneumonic lesions due to the motile bacillus is an extreme fatty degeneration of the liver, lungs, and other organs of chiefly female guinea pigs leading to death just before or after parturition. The fatty degeneration as well as the pneumonia is almost wholly limited to the winter season (December-May).

"The motile bacillus lives over from winter to winter in old pneumonic foci or in the air tubes, attached to cilia, as described by Tartakowsky. It does not occur as a parasite of the air tubes in all guinea pig populations and attempts should be made to breed from noninfested stock.

"The reason for the seasonal incidence of pneumonia is not demonstrated. It evidently depends on a variety of interlocking, external as well as internal, factors, without the help of which the micro-organisms can not multiply in the parenchyma of the lungs."

A bibliography of 24 titles is appended.

About the diagnosis of trypanoses in general and the possible differentiation of the trypanosomes causing the disease by the aid of sera from highly immunized animals, A. LANFRANCHI (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig.*, 35 (1912), No. 19-22, pp. 928-945; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 26, p. 470).—In previous work^a it was shown that nagana trypanosomes, which had been repeatedly passed through the spleens of dogs, suffered a marked decrease in virulence. By simultaneously injecting (subcutaneously, intravenously, or intraperitoneally) the dogs so treated with a slightly attenuated virus, an immune serum of high potency was obtained. The experiments have now been continued with an immune serum of this character, and tests were made with the agglutination, precipitation, and complement fixation tests for the purpose of determining whether the various trypanosomes could be differentiated from one another, especially nagana and the organism causing dourine.

The results can be summarized as follows: The serum from dogs which were highly immunized against nagana possesses a high agglutination value (1:75,000), but agglutinates *Trypanosoma brucei* and *T. equiperdum* in the same dilution and just as rapidly, consequently the method can not be used as a differential method. With the precipitation reaction, however, it was found that if nagana serum was mixed with the serum from an animal artificially infected with *T. brucei* or with *T. equiperdum* in the ratio of 1:3 a marked difference could be noted between nagana and dourine. In the case of nagana a positive reaction was obtained, irrespective of whether the serum was taken at the beginning, the height, or the end of the disease, while with dourine a negative reaction was shown at the beginning and end of the disease. Positive results at the height of the dourine infection were only obtained with guinea pigs, and only when the serum present was greater than the ratio mentioned above. The serum from mice affected with dourine was not precipitated at the height of infection, not even when a large amount of serum was added. The sera from nagana and dourine behave alike with the complement fixation reaction and react positively in all stages of the disease, consequently this can not be used for differential purposes.

^a Berlin. Tierärztl. Wchnschr., 26 (1910), No. 13, p. 285.

Tuberculosis in animals, A. E. METTAM (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1912), No. 1, pp. 114-126).—This is a clear statement of the facts regarding tuberculosis under the following headings: Cause, methods of infection (inoculation, inhalation, ingestion, urinogenital); dissemination of virus, diagnosis, clinical examination, and the elimination of tuberculosis from infected herds.

Memorandum on tuberculosis in relation to the cattle industry, J. R. CAMPBELL (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 2, pp. 235-238).—A summary of facts relating to the part which tuberculous cows play in the transmission of tuberculosis to man, especially in milk. This article is based on the findings of the Royal Commission, but more especially upon Mettam's paper noted above.

Tubercle bacilli in the circulating blood, E. QUERNER (*München. Med. Wchnschr.*, 60 (1913), No. 8, pp. 401-404; *abs. in Deut. Med. Wchnschr.*, 39 (1913), No. 11, p. 522).—The sediment obtained from the blood of 37 chronically infected human subjects was injected into animals for the purpose of detecting the virulent tubercle bacillus. Negative results were obtained, and the findings of Rumpy are criticized.

Some further investigations in regard to open liver tuberculosis in the bovine and pig, E. JOEST and M. ZIEGLER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 14 (1913), No. 1, pp. 9-40, pls. 3).—As a continuation of previous work^a, the authors report this data on the presence of tubercle bacilli in the bile of tuberculous animals for the purpose of establishing the manner in which the tubercle bacilli enter the bile and to make a histologic study of the tuberculous foci found in the liver, with particular reference to the biliary channels.

The work was carried on with the livers of 130 bovines and pigs from the Dresden slaughterhouse. In 26 cases guinea pigs treated with bovine bile died prematurely as a result of the administration of the toxic bile. These animals were not included in summing up the results of the experiments. Of the remaining 104 livers 76 (53 hogs and 23 bovines) came from animals having a local infection of the liver, and the remaining 28 came from 24 hogs and 4 bovines having a generalized tuberculosis. In 15 out of the 104 cases tubercle bacilli were detected in the gall bladder. In local tuberculous cases the animal test with guinea pigs showed positive in 8 instances (7 bovines and 1 hog), and in the generalized tuberculous cases in 7 instances (3 bovines and 4 hogs).

A tuberculous liver is supposed to be a greater factor for the expulsion of tubercle bacilli than the presence of bacilli in the arterial blood stream. Great stress is laid upon the significance of liver (open) tuberculosis as a factor in spreading the disease among animals.

About the elimination of tubercle bacilli with the bile of tuberculous bovines and goats, C. TITZE and E. JAHN (*Arb. K. Gsndhtsamt.*, 45 (1913), No. 1, pp. 35-58).—These experiments are along the same lines as those reported by Joest and Emschhoff (see above), Calmette and Guérin (*E. S. R.*, 21, p. 683), and others, and include the study of 36 bovines and 4 goats.

In the experiments it is shown that tubercle bacilli when exposed to the action of bile for 4 days lose none of their virulence. Twenty-six of the bovines under examination were cases of spontaneous tuberculosis and 11 of these were found with the guinea pig test to contain tubercle bacilli in their bile. Six of these showed pathologic changes in the liver, and 4 showed changes in the portal lymph tract. In the remaining animal, a 7-year-old, well-nourished

^a *Ztschr. Infektionskrank. u. Hyg. Haustiere*, 10 (1911), No. 4, pp. 197-206.

bull, no changes were noted either in the liver or the portal lymph glands, but the mesenteric glands were enlarged and contained cheesy foci while the bronchial and mediastinal lymph nodes showed encapsulated areas. No other changes were manifest.

Ten bovines and 4 goats were artificially infected and the biles of these were examined. Only a slight tuberculosis was induced in some of these animals, and in almost every case the bile when given to guinea pigs failed to produce tuberculosis. Six bovines were given subcutaneous and intrapleural injections and 4 bovines and 4 goats intravenous injections. One of the 4 bovines slaughtered 7 days after infection showed no lesions, and subcutaneous injections of emulsions of the kneefold and popliteal lymphatic glands, kidneys, muscles, and blood from this animal into guinea pigs did not produce the disease. A piece of the popliteal lymphatic glands, however, placed under the skin of a guinea pig produced tuberculosis in that animal. Of the other 3 animals 2 showed miliary tuberculosis with no tubercle bacilli in the blood, but 1 of the 2 had tuberculosis of the portal lymph glands.

In the 4 goats bovine tuberculosis was produced and after slaughter the organs and blood from the animals were found to be very virulent. The livers, on the other hand, were not affected. The authors conclude that infection by way of the blood stream with regard to the elimination of tubercle bacilli with the bile has not the importance which is usually attached thereto. This coincides with the views of Joest and Emshoff. Liver tuberculosis, however, should be considered when measures of control against the disease are enforced. In most cases pulmonary tuberculosis is present at the same time with liver tuberculosis.

About the experimental production of tubercular antibodies in the bovine, and a contribution to immunization against tuberculosis, E. ROTHE and K. BIERBAUM (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 19, pp. 341-344).—The purpose of this work, which was begun in 1909, was to devise a method whereby tubercular antibodies could be produced in the bovine in large amounts and in a very short time, and, furthermore, to determine if the antibodies produced had protective and curative qualities. The sera obtained in the tests were examined with the complement fixation and precipitation methods.

The results show that by a single intravenous injection of bovines (tubercular animals, nontubercular animals, animals hypersensitive toward tuberculin, and nonhypersensitive animals) with dead intact bacilli in doses of from 30 to 50 mg., it was possible to produce in the serum a large number of specific complement-fixing amboceptors and precipitins. The formation of experimentally produced complement-fixing amboceptors and precipitins was found not always to run parallel in bovines and horses.

By the repeated intravenous treatment with dead bacilli it was possible in bovines to produce a marked protection against a later infection with living, fully virulent bovine tubercle bacilli. Sera which are rich in complement-fixing amboceptors and precipitins also seem to have some influence on virulent tubercle bacilli, because after a long contact with them they appear to diminish the virulence of these organisms. The rise in temperature produced as a result of injecting the organisms has no diagnostic significance. The sera containing many tubercular antibodies can eventually be used as an indicator for the strength of various tuberculins.

Tuberculosis and pearl disease, A. BESSERER (*Festschrift 84. Versamml. Deut. Naturf. u. Ärzte von der Med. Naturw. Gesell. Münster, 1912, pp. 388-404*).—Cultures were obtained from 23 human tuberculous patients. The majority of these were cases of pulmonary tuberculosis, while the remainder consisted of cervical, intestinal, kidney, and brain tuberculosis. The cultures

were compared with the bovine type of tubercle bacillus obtained from the Institute of Infectious Diseases at Berlin. All of the cultures were first examined to see whether there were any atypical strains among them. In addition, the Theobald Smith acid curve was noted. The latter method is recommended on account of its simplicity and accuracy.

In all, 116 rabbits were vaccinated with the human strain. Sixty-seven of these received subcutaneously 0.001 gm. of pure cultures. No animal died from tuberculosis but 16 died spontaneously from coccidiosis and a few from pneumonia and a rabbit disease. In 40 per cent of the cases on autopsy submiliary to pinhead size tubercles were present in the lungs. In the animals which were killed at a later date evidences of healing were often seen. No tuberculosis of the glands or kidneys (which is often noted in the group of rabbits treated with the bovine culture) was ever seen in the animals treated with the human cultures.

Three pure cultures obtained by the antiformin method gave the characteristics of the human tubercle bacillus, but when injected they had no effect upon the lungs of rabbits and consequently it is concluded that antiformin injures the tubercle-producing powers of the organism.

Several pages are devoted to the variability factor and the frequency which the bovine type of organism is detected in the sputum of man when affected with tuberculosis.

The specific paratuberculous enteritis of cattle in America, K. F. MEYER (*Jour. Med. Research*, 29 (1913), No. 2, pp. 147-189, pl. 1).—"The paratuberculous enteritis found in America is identical with the disease of European countries. By intravenous inoculations with material from the mesenteric lymph nodes, the disease has been reproduced in young calves (30, 92, and 96 days of age). The incubation time was from 4 to 8 months. One animal died from the disease 12 months after the infection. Feeding experiments were not successful. The natural infection probably takes place in the early days of life by contact with infected mothers or surroundings. The possibility of an infection in certain pastures, where *B. paratuberculosis* leads a saprophytic life, can not be denied, and is probably of importance for the infection in adults. *B. paratuberculosis* can be cultivated on solid and liquid culture media containing glycerin extracts of acid-fast bacilli, particularly tubercle bacilli of *B. phlei*. Six strains have so far been isolated. The growth is slow and only possible at body temperature. A culture medium consisting of equal parts of tuberculin and bouillon, with 2 per cent agar and 1 per cent serum, is the best for primary isolations. The use of antiformin should be limited to contaminated material.

"The bacterioscopic examination of feces and rectal scrapings is only of diagnostic value in about 40 per cent of the cases in the advanced stages of the disease. Avian tuberculin is an unreliable reagent for paratuberculosis. 'Paratuberculin,' and perhaps some of the serum tests, may prove in the future to be more reliable. *B. paratuberculosis* is, in certain respects, related to different representatives of the acid-fast group of bacteria."

A bibliography of 33 titles is appended.

The persistence of the bacillus of infectious abortion in the tissues of animals, W. E. COTTON (*Amer. Vet. Rev.*, 44 (1913), No. 3, pp. 307-318).—"The conclusions drawn from this paper, presented at the fiftieth annual meeting of the American Veterinary Medical Association in New York, September, 1913, are as follows:

"The bacillus of infectious abortion, or at least the strains with which the experiment station has worked, may, and in most cases does, persist in the udders of cows that have aborted for years and possibly for the balance of

their lives; and during this time is eliminated more or less continuously with their milk. It may make its appearance in the milk months before abortion occurs, even before a conception that is terminated by an abortion. It may be eliminated for years from the udders of cows that never aborted. It may persist in the genital tract for as much as 46 days after an abortion; and the bacilli contained in uterine discharges may resist the action of sun and weather for at least 10 days. It may appear in the placenta of a normal pregnancy subsequent to an abortion. It may persist in the spleens of inoculated guinea pigs in which there are lesions for 77 weeks, and in the spleens of inoculated rabbits for 19 weeks, without producing lesions."

See also a previous note (E. S. R., 29, p. 778).

The poisoning of cattle in the pasture, C. K. FRANCIS (*Oklahoma Sta. Rpt. 1913, pp. 20-29, figs. 2*).—This is a general review of the subject with references to and quotations from the literature. It is stated that there are periods during the year when almost every mail brings one or more reports of animal poisoning, the number of animals dying suddenly in Oklahoma each year being very large.

The author's investigations have shown hydrocyanic acid to be present in Kafir corn at every stage, except the mature stage. "From all data recorded it appears that stunted plants showing the need of rain are especially dangerous. All young growth of the sorghum group are liable to contain the poison. The second growth and frosted plants have also been shown to be unsafe. The samples containing the larger amounts of prussic acid were very bitter to the taste, and this characteristic may be used as a rough test of the condition of the plants. If it is necessary to pasture stock in fields while the growth is at the various stages mentioned, the animals should be allowed to remain but a few minutes at first, or the material tested by turning in an animal of little value. If a hungry animal refuses to feed on green plants, you may be certain that they are not safe."

The morphology of the sheep tapeworm (*Thysanosoma actiniodes*), L. D. SWINGLE (*Wyoming Sta. Bul. 102 (1914), pp. 103-116, figs. 31*).—While the fringed tapeworm of sheep, as it is commonly called, is very prevalent in Wyoming, most of the sheep slaughtered at Laramie being infected, neither its anatomy nor life history has been worked out. The present paper consists entirely of an illustrated report of studies of its anatomy.

Effect of dips on wool, C. MALLINSON (*Agr. Jour. Union So. Africa, 6 (1913), No. 4, pp. 671-678*).—The author, a sheep and wool expert, reports that during a trip to Great Britain he failed to hear of any serious complaint about the scouring of South African wool or of any difficulty in dyeing. He recommends that South African farmers continue to dip for scab as recommended by the department of agriculture.

The prophylaxis, serum-therapy, and serovaccination of contagious agalaxia, H. CARRÉ (*Rev. Gén. Méd. Vét., 20 (1912), No. 238, pp. 529-538; abs. in Jour. Compar. Path. and Ther., 26 (1913), No. 1, pp. 67-69*).—It is shown by this work that the mammary secretion may be infectious for months and even up to the time when there is complete atrophy of the gland. That the milk does not rapidly lose in virulence is shown by the fact that an infected milk, kept for 8 days at room temperature during the month of August, when injected into the teat of a goat produced a typical attack of the disease. In every flock examined the occurrence of the disease was observed to follow the introduction of new animals from the outside. Attendants also carried the disease from one flock to the other.

Some experiments regarding serum-therapy and serovaccination against the disease were conducted. "In the first flock there were 34 diseased and 80

healthy animals. Of these latter 60 were given 5 cc. of protective serum subcutaneously, the others being kept as controls. Three weeks later 7 of the control animals were affected, but all those that had received a dose of serum had escaped infection. In view of the fact that the immunity conferred by the serum was effective for 2 to 4 weeks only, an attempt was made to prolong the period by giving an inoculation of serum and virus mixed. The 60 animals were therefore given 5 cc. of serum mixed with $\frac{1}{10}$ cc. of virulent pleural exudate from an experimental case. Two months later it was reported that none of the protected animals had become infected, while the control animals had.

"A second flock was divided into 2 lots of 100 animals each, which were placed in folds about 200 yds. apart. The disease broke out in a severe form in 1 of the folds, and within 3 weeks 40 of the animals were dead, and the others were in a very poor condition. The flock in the second fold remained free of the disease. Contagion was, however, inevitable, as the same persons attended both lots of animals. The whole of the healthy batch received 5 cc. of serum subcutaneously, but a week later 2 animals were found to be diseased. In the author's opinion these animals were in the incubation state when the serum injections were given, and the fact that they contracted the disease showed that the fold was infected. The same day 50 healthy adult animals in the fold were given a dose of serum and virus as in the case of the first flock mentioned. At the request of the owner 10 of these animals were placed with the infected batch. None of the vaccinated animals had contracted the disease 2 months later. Even those placed with the diseased animals had remained free.

"A third flock numbering 110 ewes contained 2 diseased animals. Serovaccination was practiced on the whole flock, and no fresh cases had appeared up to 3 months later."

From the experiments the author concludes that the antiagalaxia serum possesses immunizing properties, but it seems to be without value when given during the period of incubation or after the symptoms have appeared. Serovaccination prolongs the immunity conferred by the serum alone, but the duration of the immunity so produced has not been established. It is of sufficient length, however, to allow an epidemic to die out.

Spirochetes in hog cholera, G. ARNHEIM (*Ztschr. Hyg. u. Infektionskrank.*, 76 (1914), No. 3, pp. 435-437).—Hog cholera, according to this investigation, is not caused by spirochetes. The findings of King, Baeslack, and Hoffmann (*E. S. R.*, 29, p. 681) are criticized on the ground that up to this time spirochetes have not been filtered under pressure, and furthermore, that salvarsan, a well-known spirochete poison, is not of any value in hog cholera. In the hog cholera virus, however, certain transitional forms were noted.

From the blood taken from the tails of infected hogs spirochetes were found, but none were noted in the blood obtained by puncturing the heart. Spirochetes were also noted in the intestinal tract where a slight intestinal diphtheria was present. From the mesenteric lymph glands of a pig dying of hog cholera and a severe intestinal diphtheria the same spirochete could be obtained by cultivation by Schereschewsky's mixed culture method.

The spirochetes found in hog cholera are believed to originate from the intestines.

Hog cholera investigation, R. A. CRAIG (*Indiana Sta. Rpt.* 1913, pp. 76-79).—In testing the comparative virulence of the virus in blood, urine, and filtered and unfiltered salt solutions from cholera hogs, pigs weighing from 30 to 60 lbs. were injected intramuscularly. Pigs inoculated with the virus in blood lived an average of 12.08 days; those with virulent salt solution, 12.92 days;

those with the filtrate of virulent salt solution, 12.37 days; and those with urine, 13.54 days. The author has been unable to attenuate the hog cholera virus in either blood or salt solution so as to produce a successful vaccine. He states that virulent salt solution obtained from hogs fatally sick with hog cholera 3 hours after a physiological salt solution has been injected into the abdominal cavity at the rate of 10 to 20 cc. per pound of body weight is now being made use of in the production of hyperimmunes by the intramuscular method.

Cholera vaccination and carcass values, O. W. JOHNSON (*Breeder's Gaz.*, 65 (1914), No. 2, p. 60).—The author presents evidence to show that some of the hog cholera serum which has been used in Iowa contains pyogenic organisms. In certain herds given special care during the treatment nearly all the hogs had abscesses form, while in other herds in which less care was taken, the hogs have been nearly free from abscess formation.

Suptol in acute swine plague, WELDES (*München. Tierärztl. Wchnschr.*, 56 (1912), No. 24, pp. 425-427; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 24, pp. 438).—In one barn hogs were given curative treatment for acute swine plague and with satisfactory results. With 100 hogs, which had the chronic form of the disease, partly good and partly unsatisfactory results were obtained.

Studies on the etiology of epizootic abortion in mares, K. F. MEYER and F. BOERNER (*Jour. Med. Research*, 29 (1913), No. 2, pp. 325-366, pls. 2).—"In an outbreak of epizootic abortion in mares in Pennsylvania it was proved by our investigations that the causative agent was a bacillus belonging to the subgroup C of the paratyphoid-enteritidis group. For this bacillus we propose the name *Bacillus abortus equi*. *B. abortus equi* fulfils all the requirements of the organism belonging in the paratyphoid B group, but the growth on the slanted agar being membranous, dry, and brittle, and there being a considerable amount of gas production in dulcete, these can be used for differentiation. *B. abortus equi* is agglutinated by a paratyphosus B, or enteritidis (Gaertner) serum, only in low dilutions.

"With cultures of the organism, abortion could be produced by the subcutaneous, intravenous, intravaginal, and alimentary infection in a pregnant cow, goat, sow, and small animals like guinea pigs and rabbits. The average incubation time was 15 days. *B. abortus equi* is pathogenic for guinea pigs, rabbits, mice, rats, and pigeons. The anatomical lesions are similar to those seen in paratyphoid infections. Rabbits are more susceptible to the infection than guinea pigs. Agglutination and complement fixation are suitable methods for determining the existence of an infection by *B. abortus equi*. Further investigations are necessary to prove the existing theories of natural infection."

A bibliography of 16 titles is appended.

Blackhead of turkeys, H. J. WHEELER (*Rhode Island Sta. Rpt. 1912*, pp. 205-209).—The author reports that studies of the past 2 years under the direction of P. B. Hadley have demonstrated conclusively that blackhead of turkeys is a pathological condition related etiologically to at least 2 species of protozoan parasites, namely, *Eimeria avium* and a flagellated organism still unknown except in a few stages of its development. A large number of experiments show that it is practically impossible in Rhode Island for young turkeys to escape the blackhead parasites. Work carried on with intestinal antiseptics, chiefly with Formidine and Resor-bisnol, has thus far given rather unfavorable results. While post-mortem examinations indicate that Formidine serves to reduce the severity of the cecal lesions, it does not appear to have favorably modified the lesions of the liver which may be present without any pathological condition of the ceca.

In studies of the coccidium and flagellate in artificial culture alkaline media furnished a condition favorable to rapid development, while acid media restricted development. Milk soured by means of inoculation with pure cultures of a strongly acid producing micro-organism (*Bacterium bulgaricum*) was fed in large amounts. It is relished by the poults and up to the time of writing has shown a marked tendency to prevent manifestation of the severe clinical symptoms and pathological appearances of the disease, at least during the early critical period (thirty-fifth to fiftieth day).

The parasitocides, A. RICHAUD (*Arch. Par.*, 16 (1913), No. 1, pp. 5-133).—A series of lectures by the author.

RURAL ENGINEERING.

American irrigation farming, W. H. OLIN (*Chicago*, 1913, pp. 364, pls. 57, figs. 5).—This book treats the history of irrigation developments, the fundamental terms in irrigation practice, soil study, seed bed preparation, seed selection, methods of water distribution, cropping "under the ditch" with special reference to alfalfa, potatoes, small grains, sugar beets, orchards, trucking, forage crops, crop rotations, and live stock, concluding with statistical data relating to the Reclamation Service and its work, rules for measurements, and other tabular matter. A bibliography of 88 titles of agricultural books is appended.

Irrigation in the British Indies, A. NORMANDIN (*Bul. Écon. Indochine*, n. ser., 16 (1913), No. 103, pp. 618-756, pl. 1, figs. 41).—This report describes the geography, meteorology, geology, agricultural conditions, and irrigation possibilities of the region and discusses in some detail irrigation technique, finance and economy, cost of construction and maintenance of irrigation works, irrigation by pumping, private irrigation systems, drainage of irrigated lands, and flood protection. In addition some of the unfinished irrigation works of the region and their irrigating possibilities are described.

Irrigation works, E. S. BELLASIS (*London and New York*, 1913, pp. VII+199, pls. 6, figs. 33).—This book deals with the principles governing the design and management of irrigation works, refers to irrigation works of various countries, and particularly discusses the canals of northern India as a basis for the principles and methods to be adopted in the design and improvement of irrigation channels.

Irrigation and water conservation in western Australia, H. OLDHAM and J. F. MOODY (*Perth, Aust.: Dept. Agr. and Indus.*, 1913, pp. 37).—The possibilities existing in western Australia relative to the development of water resources, especially for irrigation purposes are discussed, and in this connection attention is drawn to the many natural advantages of the region and to the need for their use in the promotion of settlement under methods of intense culture. Descriptions are given of several existing irrigation systems in different parts of the world to illustrate the possibilities in this direction.

Hints on irrigation.—Pumping plants, W. M. WATT (*Rhodesia Agr. Jour.*, 11 (1913), No. 1, pp. 52-63).—Information is given which is intended to guide farmers in the selection and proper erection of small pumping plants for irrigation purposes in Rhodesia.

Spraying systems in the Province of Posen, F. SCHEEFFER (*Maschinen Ztg.*, 11 (1913), No. 21, pp. 252-254, figs. 3).—Two different systems of spray irrigation are described, in both of which a system of mains is placed underground and fitted with hydrants at convenient intervals. The spray apparatus carried on trucks is connected to the hydrants by portable pipe lying in sections so

as to be easily disconnected and moved to different parts of the field. Trials of these systems showed them to be fairly satisfactory but relatively expensive.

Causes of inefficiency of irrigation, A. S. GIBB (*Engin. Rec.*, 68 (1913), No. 22, pp. 608, 609, fig. 1).—In an investigation of the causes which influence the economical application of irrigation water on a large irrigation system of the Punjab in India, it was found that the degree of liberality of water allowance is the main factor causing the rapid rise of underground water level and consequent water logging of the soil and the waste of large quantities of irrigation water. To remedy these conditions it is concluded that a little can be done by educating all the cultivators up to the standard of the best and by subdividing the lands so as to suit the most economical discharge of water, but that much more can be effected by increasing the accuracy with which the water is distributed to the lands of the cultivators.

Silting in the Shabshir and Ikhnawai canals, K. O. GHALEB (*Cairo Sci. Jour.*, 7 (1913), No. 84, pp. 194-200, pls. 3, fig. 1).—Mechanical analyses were made of the silt samples taken at various points in the deposits in these canals, from which the nature and cause of the silting and the necessary remedies were determined.

Metal flumes for irrigation canals, F. W. HANNA (*Engin. News*, 70 (1913), No. 22, pp. 1077-1079, figs. 6).—This article deals with the factors governing the design and construction of 3 general types of semicircular metal flumes, namely, the rough transversely corrugated interior, semirough interior, and the smooth interior types. Methods of metal flume design and construction employed on the Boise irrigation project are described.

Drainage and irrigation: Approximate formula and table for proportioning priming pumps for centrifugal pumping plants, C. R. SESSIONS (*Engin. and Contract.*, 40 (1913), No. 23, pp. 628, 629, fig. 1).—An approximate formula is derived and tables given to serve as a guide in properly proportioning or selecting an air pump for priming centrifugal pumps.

Drainage, W. O. HOTCHKISS, E. M. GRIFFITH, and E. R. JONES (*Rpt. Conserv. Com. Wis.*, 3 (1912), pp. 52-60, fig. 1).—It is stated in this report that the marsh lands which it is possible to drain in Wisconsin comprise nearly 3,000,000 acres, or about 7.8 per cent of the total area of the State. The three possible uses to which these lands may be put are discussed as for agricultural purposes, for sources of peat, and for reservoirs for the regulation of stream flow both for the benefit of water power and the prevention of floods. Recommendations are made regarding suitable changes in the drainage laws of the State.

The drainage of wet and marshy lands for agricultural purposes, E. R. JONES (*Rpt. Conserv. Com. Wis.*, 3 (1912), pp. 61-67).—In connection with the drainage of swamp lands the author points out the agricultural value of muck and peat.

Soil drainage, A. G. MCCALL (*Fruit World Austral.*, 14 (1913), No. 4, pp. 98-104, figs. 12).—This briefly reviews the fundamental and practical considerations in proper soil drainage, calls attention to the benefits derived from the draining of alkali soils, and includes an article on good effects of tile drainage, by R. M. Dolve.

A method of making rough estimates for roads in hilly country, J. D. MAITLAND-KIRWAN (*Indian Forester*, 39 (1913), No. 10, pp. 477-486, figs. 5).—The operation of a handy instrument for use in preparing estimates for roads running along moderately steep hillsides in cut is described.

Economic results of surface tarring, E. GUGLIELMINETTI (*Good Roads, n. ser.*, 6 (1913), No. 10, pp. 111, 112).—In a paper presented at the Third International Road Congress, London, it is concluded that surface tarring does not

give such appreciable results on metaled roads with heavy vehicles and intense traffic as on metaled roads with a moderate traffic, since the metaled road itself does not wear well under heavy vehicles and intense traffic. To obtain good results it is not only necessary "to adopt a good system of surface tarring but the roads on which it is done must be selected judiciously."

Concrete highways (*Philadelphia, 1913, pp. 114, figs. 62*).—This pamphlet deals with the design and construction of concrete highways and with different types of wearing surfaces. Specifications are included for 1- and 2-course pavements, bitumen and sand wearing surfaces, and reinforced concrete pavements.

The effect of salts upon the strength of concrete cured at low and normal temperatures, H. E. PULVER (*Wis. Engin., 18 (1913), No. 1, pp. 6-13, figs. 4; abs. in Cement Era, 11 (1913), No. 11, p. 41*).—Tests are reported which were conducted to determine the effect of sodium chlorid and calcium chlorid separately and together on a 1:2:4 concrete, cured at normal room temperature and at temperatures below freezing. The salts were dissolved in the mixing water in the following percentages by weight: Sodium chlorid 6, 9, 12, and 15; and calcium chlorid 2, 4, 6, 8, and 10.

The results show that the strength of the concrete cured under normal temperature decreased as the percentage of sodium chlorid increased. For the concrete cured at low temperature there was an increase in strength for the addition of sodium chlorid up to 12 per cent after which there was a decrease. The addition of calcium chlorid increased the strength of this concrete up to about 4 per cent at which point the maximum strength was reached.

Serious disintegration was observed on the surfaces of cubes cured at low temperatures and containing 6, 8, and 10 per cent of calcium chlorid. The best effect was obtained at low temperatures by using both sodium chlorid and calcium chlorid in the mixing water, a 2 per cent calcium chlorid and 9 per cent sodium chlorid mixture giving the best results.

Explosives in agriculture, F. R. TRELEAVEN (*Queensland Agr. Jour., 31 (1913), No. 4, pp. 201-204*).—From the successful results of "experiments carried out covering a period of the past eleven years", the author briefly reviews methods of using both nitroglycerine and chlorate compounds for land clearing, subsoiling, log splitting, ditching, and drainage. He recommends the chlorate compounds for the heavier blasting on account of their higher rending and energy retaining powers.

Electricity for the farm and home, F. KOESTER (*New York, 1913, pp. XX+279, pl. 1, figs. 53*).—This book includes the following chapters: Benefits of agricultural electricity, central station service, generating electric power, electric motor applications, cost of operating, electricity in the manufacture of farm by-products, electricity in the preservation of farm products, electric transportation of farm products, electric plowing, diverse applications of electricity, electric heating, electric lighting, the telephone in rural communities, electric power in irrigation, and electric stimulation of vegetation.

Economics of rural distribution of electric power, L. E. HILDEBRAND (*Univ. Mo. Engin. Expt. Sta. Bul., 4 (1913), No. 1, pp. 50, figs. 12*).—This paper is primarily a discussion of the economic problems of the rural distribution of electric power and is intended to be of interest to farmers, central station managers, and engineers. It takes up in some detail the application and advantages of electric power to farms, discussing these questions from the standpoint of private and isolated generating plants on the one hand and rural distribution systems on the other. Typical installations of both systems are described and the fundamental, technical, and practical points to be considered in the design and installation of a rural electric distribution system are out-

lined in some detail. In connection with the practical application of electric power to the belt work of farms a table of useful data is given showing the amount of power required and the cost of performing several farm operations at various rates.

It is concluded that electric motors can be profitably used almost daily in many farm processes because of their convenience, ease of operation, flexibility, lack of noise and dirt, long life, small repair charges, and general economy, but that it is usually uneconomical for farmers to own and operate isolated plants since the fixed charges are high and such plants are not well adapted to supplying motors with power. It seems preferable and more profitable to distribute power from a central electric plant by means of a high voltage distribution system. "The best system will usually be found to be a three-phase system, either 3 or 4 wire, with a voltage such that standard 2,200 or 6,600 volt distributing transformers can be used."

Small central stations supplying power to farmers only and with no other market are not thought to prove successful financially. Distribution from a city central electric station or a long distance high voltage transmission line is recommended where feasible.

Mechanical efficiency of gasoline engines, S. F. WILSON (*Power*, 38 (1913), No. 18, p. 605).—A method for closely approximating the mechanical efficiency of gasoline engines of the hit-and-miss type with constant gasoline level feed is suggested which is based on the number of explosions at full and no load. The formula for this method is: $\text{Mechanical efficiency} = \frac{Ne - No}{Ne}$. In this formula Ne equals the number of explosions per minute at full load and No equals the number of explosions per minute at no load.

Thrashing with steam engine or electric motor, P. TIETZ (*Deut. Landw. Presse*, 40 (1913), Nos. 82, pp. 979-981; 83, pp. 995-997).—Comparative tests were made of steam and electric power for thrashing on 2 farms. On the first farm a thrasher with a 22 by 60 in. cylinder was driven by a 32 h. p. electric motor and by a 25 h. p. portable steam engine. On the second farm a thrasher with a 24 by 66 in. cylinder was driven by a 40 h. p. motor and a 31 h. p. portable steam engine.

The results show little difference in the amounts of grain lost by the 2 kinds of power, the loss being below 0.3 per cent in both cases. The results on cost per horsepower hour, total accomplishment, speed, efficiency, etc., show that in both sets of tests the steam engines were essentially cheaper and more efficient than the electric motors.

The present state of motor cultivation in Germany, G. FISCHER (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 6, pp. 852-858, pls. 3).—The author describes and compares a few German makes of motor plows and motor scarifiers and also some American makes of plows and tractors which have proved most successful in German agriculture.

He states that the so-called "Stock" motor plow has given the best results technically and practically as a cheap mechanical plow suited to small farms and to the shallow tillage of light soils. A summary of results obtained with motor plows in Germany shows that for shallow and moderately deep plowing of light and medium soils some very useful machines exist. Gradients above one in ten and numerous big stones are said to offer considerable difficulties, although the American plows are for the most part protected from breakage by stones by means of wooden pegs. The American tractors are said to work best on hard soils, while on soft soils plows of the Stock type are preferable. Disk plows are said to penetrate more easily to considerable depth than the other types.

Rope and its use on the farm, J. B. FREAR (*Minnesota Sta. Bul. 136, pp. 76, figs. 180*).—This bulletin is intended to cover briefly the materials, methods of manufacture, strength, and use of rope in general farm work, and to give "that information which is necessary for a thorough understanding of rope." A section on general information includes the construction of rope, sources of fiber, calculation of weight, care of rope, uncoiling rope, relaying an untwisted rope, principles and elements of a knot, strength of rope, and calculation of strength.

"Four-strand ropes have about 16 per cent more strength than three-strand ropes. Tarring rope decreases the strength by about 25 per cent because the high temperature of the tar injures the fibers." The breaking strength in pounds for new Manila rope "may be found approximately" by the formula $S=D^2 \times 7,200$, and for hemp rope $S=D^2 \times 5,400$, where S equals the breaking strength and D the diameter in inches. "The safe load is usually regarded as one-sixth of the breaking strength."

Other sections describe in detail, with many illustrations, preventing the ends of rope from untwisting, knots for tying ropes together, loops at the rope's end, loops between the rope's ends, hitches, halters and halter ties, and splices. The final section takes up blocks and tackle, discussing particularly the lifting force of blocks and maximum and safe loads. A bibliography is appended.

RURAL ECONOMICS.

Studies in agricultural economics (*Bul. Univ. Tex., No. 298 (1913), pp. 132*).—This bulletin contains a collection of papers dealing with economic conditions in Texas. The subjects treated are as follows: The Crop Mortgage System in Texas, by S. J. Joekel; The Need and Possibility of Cooperative Rural Credit in Texas, by L. H. Haney; Cooperative Agricultural Credit, by W. Trenckmann; Cooperative Production by Farmers, by C. E. Lamaster; Cooperative Marketing of Fruit, Truck, and Cotton, Chiefly in Texas, by G. Wythe; Farmers' Educational and Cooperative Union in Texas, by H. L. Voorhies; Seasonal Industries and their Labor Supplies in Texas, by W. E. Leonard; The Farm Labor Problem, by S. M. Leftwich; A Study in Highway Administration with Special Reference to Texas' Needs, by M. H. Griffin; Railway Rates and Services as affecting the Texas Farmer, by F. L. Vaughan; The Theory and Practice of Speculation on Produce Exchanges, by R. Randolph; Farm Tenure in Texas, by W. T. Donaldson; and Our System of Taxation and its Effect on the Farmer, by B. E. Dailey.

Agriculture.—Questions of the day (*X. Cong. Internat. Agr. Gand, 1913, Compt. Rend., pp. 319–326*).—This volume contains abstracts of the papers on subjects relating to rural economics at the Tenth International Congress of Agriculture at Ghent, previously noted (*E. S. R., 29, p. 101*).

[Immigration and agricultural workers], J. A. HILL (*U. S. Senate, 61. Cong., 2. Sess., Doc. 282 (1911), pp. 60–69*).—According to the census of 1900 of the foreign born male breadwinners 21.7 per cent were engaged in agriculture, and of those born in the United States of foreign parentage 25.9 per cent. The second generation of every nationality is engaged in agriculture to a greater extent than the first generation, although those of German and Irish parentage, who comprise more than half of the breadwinners, do not show as strong a tendency as those of other parentage. The following table brings out the fact that for every aged group a larger percentage of the second generation than of the first are farmers.

Percentage of total male breadwinners of the same age engaged in agriculture.

Age	Foreign born, white.		Native white, foreign born parentage.	
	Farmers.	Agricultural laborers.	Farmers.	Agricultural laborers.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
10 to 15 years.....		17.4		35.6
16 to 24 years.....	2.1	13.0	4.0	21.6
25 to 34 years.....	8.3	5.3	14.1	7.4
35 to 44 years.....	13.7	3.1	20.2	3.4
45 to 54 years.....	20.1	2.8	24.2	2.8
55 to 64 years.....	26.8	3.2	30.0	3.0
65 years and over.....	34.5	4.7	37.7	3.9
Total, 10 years and over.....	14.6	5.2	13.3	11.6

Fecundity of immigrant women, J. A. HILL and J. H. PARMELEE (*U. S. Senate, 61. Cong., 2. Sess., Doc. 282 (1911), pp. 733-826*).—This investigation, based upon the census returns for 1900, brings out, among other facts, that women in cities bear fewer children than those in the rural districts. The variations are illustrated in the following table:

Average number of children born to women under 45 years of age, married 1 to 19 years.

Nativity.	Average number of children born.			
	Ohio.		Minnesota.	
	Cleveland.	Rural counties.	Minneapolis.	Rural counties.
Native white of native parentage.....	1.6	2.4	2.4	3.4
White of foreign parentage.....	3.0	3.1	3.8	5.2
First generation.....	3.4	3.5	4.0	5.5
Second generation.....	2.2	2.9	3.4	4.7

Comparative fecundity of women of native and foreign percentage in the United States, J. A. HILL (*Quart. Pubs. Amer. Statis. Assoc., n. ser., 13 (1913), No. 104, pp. 583-604*).—The data contained in this article are noted above.

The labor problem, J. LAMBIE (*Scot. Farmer, 22 (1914), No. 1099, pp. 83-85*).—After noting the changes that have taken place in Scotland between the land owning class and the agricultural laborer the author calls attention to the various schemes for improving the laborer's position. Data are given showing the average earnings of agricultural laborers in England and Scotland from 1860 to 1899.

[Land mortgage reform enacted by Wisconsin] (*Orange Judd Northwest Farmstead, 12 (1914), No. 6, p. 162*).—In Wisconsin a land mortgage association may be formed by no fewer than 15 adults with a capital stock of not less than \$10,000. It may take as security for loans a first mortgage upon agricultural lands, forest lands, or lands occupied by dwellings within the State, at not to exceed 65 per cent of the value if improved, or 40 per cent if wholly unimproved. "No single loan shall exceed 15 per cent of the company's capital and surplus. All such farm mortgages shall contain provisions for proper soil

conservation, and for annual or semiannual reduction of principal (amortization)."

Two of these associations have been organized, one at Eau Claire and the other at Marinette.

Some parcel post marketing experiments, J. R. BECHTEL (*Market Growers Jour.*, 14 (1914), No. 3, p. 83, fig. 1).—An experiment conducted by the Pennsylvania State College demonstrated that greenhouse tomatoes could be marketed by parcel post with but little loss. This loss was due principally to jamming in mail bags, and could have been greatly reduced by the use of hampers.

[Cooperative marketing of creamery butter], R. C. PORTS (*Oklahoma Sta. Rpt.* 1913, pp. 12-17).—On account of a decrease in the amount of butter manufactured at the station creamery the cost of manufacturing increased from 2.6 cts. per pound for the fiscal year 1908 to 6.73 cts. per pound for the fiscal year 1913. In order to decrease the cost of distribution the station creamery united in 1909 with 5 local creameries and concentrated their shipments at Stillwater. This resulted in lower freight cost, faster and better freight service, the butter arriving at the market in better condition, better sales from commission houses, and in each creamery receiving the benefit of improved marketing facilities from both the railroad and the commission house. The net saving in freight on 8 carloads was \$65.34 per car.

[Cow insurance club] (*Jour. Bd. Agr. [London]*, 20 (1913), No. 8, pp. 730, 731).—In this club there are 124 members, mostly small holders, and 274 cows insured. Only cows and heifers are insured. The average death rate per annum is 2.7 per cent. Three-fourths of the market value of any cow that dies from disease or accident is paid, the average being £10 14s. After the sale of the carcass the average net loss per cow insured has averaged 5s.

Pig insurance clubs in 1912 (*Jour. Bd. Agr. [London]*, 20 (1913), No. 8, pp. 721-729).—A report for 1911-12 shows that there were 31 registered pig insurance societies. The average number of pigs on which claims were paid was 160 and the average death rate percentage per annum 4.8, the average amount paid per pig that died £1 17s., and the average per pig insured 1s. 9d. The income from these societies slightly exceeded the expenditures, thus establishing a reserve fund for future use. There were also 832 unregistered pig clubs, having a total of 30,529 members and 53,981 pigs insured, the average annual death rate being 5.3 per cent. These societies are reported in satisfactory financial condition.

Provisions are made by which a small society which finds itself in financial stress by reason of continued outbreaks of diseases may reinsure through the larger cooperative insurance societies.

It is concluded that a society in normal condition would find it safe to insure its members' pigs at a rate of 2s. per market pig per annum and of 1s. per pig per annum for management expenses.

Agricultural associations of the Mohammedans of Maghreb, L. MILLIOT (*L'Association Agricole chez les Musulmans du Maghreb. Paris, 1912, pp. XVI+301*).—The author describes the influence of the character and religion of the Mohammedans upon the organization of agricultural associations in this district, and gives an extensive bibliography relating to agriculture and the various types of organizations.

The agricultural outlook (*U. S. Dept. Agr., Farmers' Bul.* 570 (1913), pp. 35).—The total farm value of all crops for 1913 is estimated at \$6,100,000,000, and the value of animals sold and slaughtered and of animal products at \$3,650,000,000.

Upon the assumption that 48 per cent of the crops and 80 per cent of the animal products are sold off the farm, the average farm income in cash is estimated as \$892. This estimate, as worked out for geographical divisions, is shown in the following table:

Estimated value of sales of crops and live-stock products in the United States in 1913.

Division.	Estimated value, in millions of dollars, of farm sales from 1913 crop.			Estimated value of total sales per farm.	Estimated total sales per capita of rural population (excluding towns).
	Crops.	Live-stock products.	Total.		
New England.....	\$186	\$374	\$560	\$834	\$100
South Atlantic.....	570	186	756	657	97
North Central, east.....	410	701	1,111	950	152
North Central, west.....	956	934	1,890	1,629	273
South Central.....	615	449	1,064	516	92
Western.....	191	275	466	1,195	155
United States.....	2,928	2,919	5,847	892	139

From a study of the total production and total values, it is pointed out that it does not necessarily follow that an increased production would result in an increase in cash income per farm or per capita of farm population, or that the price paid by the consumer would be any lower. The prices of the 14 principal crops averaged 20.2 per cent higher than a year ago and 4.6 per cent higher than two years ago; their total values averaged 3.8 and 7.6 per cent, respectively.

The first annual inquiry to determine what percentage of the apple crop is shipped out of the counties where grown showed that of the production for 1913, 41 per cent was shipped out and 59 per cent retained for local consumption.

Statistics are also given of the acreage, production, and value of farm crops, index figures of yield per acre of the principal farm crops, a brief statement of the foreign trade, and wages of farm labor. Statistical tables are included showing the estimated acreage, production, and value for 1912 and 1913 of the leading farm crops. The area and condition of winter wheat and rye are also noted.

[Agricultural statistics for Scotland], J. M. RAMSAY (*Agr. Statist. Scotland, 1 (1912), pts. 1, pp. 96; 2, pp. 97-168*).—Statistics for 1911-12 are given, showing by counties the acreage, production, and average yield of the principal field crops, the number of live stock, and the number of holdings by tenure. For Scotland as a whole the duration of the harvest, weight of grain per bushel, value of crops, and weather conditions for the year are discussed.

German agriculture (*Die Deutsche Landwirtschaft. Berlin, 1913, pp. 279, pls. 22, figs. 16*).—This report of the work of the Imperial Statistical Office describes and analyzes the statistics collected by the German Government that relate to agriculture. It is principally devoted to a discussion of the census of 1907 and of additional information from other sources relating to prices, live stock slaughtered, average yields, markets, etc.

Agricultural statistics (*Zeml. Statist. (Statist. Agr.), 1911, pp. 117*).—Data are given showing by arrondissements and departments the area and produc-

tion of the principal farm crops for 1911, and for Bulgaria as a whole for 1907-1911.

The evolution of agriculture in Spain, F. ESPINOSA (*Prog. Agr. y Pecuario*, 19 (1913), Nos. 843, pp. 661-663; 845, pp. 695, 696; 846, pp. 709-711).—The author traces the history of agriculture in Spain, shows the influence of the Romans and Arabs, and gives the principal crops and the changes in the systems of cultivation for each period in its development.

Agricultural reform in Russia (*La Reforme Agraire en Russie*, St. Petersburg: Min. Agr., 1913, pp. [34], pls. 12).—This volume contains 24 tables and diagrams, with a text accompanying, to show the principal results obtained by the agrarian commissions between 1907 and 1911 in the reorganization of agriculture in Russia.

[Agriculture in Australia], G. H. KNIBBS (*Off. Yearbook Aust.*, 6 (1901-1912), pp. 265-444, figs. 6).—This section of the Australian Yearbook treats of land tenure and settlement and pastoral and agricultural production, and traces the history of agriculture in the various colonies from their early settlement to the present time. The text is fully illustrated by maps, diagrams, and statistical data.

[Agriculture in Korea] (*Ann. Rpt. Reforms and Prog. Chosen (Korea)*, 1911-12, pp. 149-167, pls. 4).—It is reported that the production of rice, wheat, barley, white beans, and native cotton increased more than 35 per cent between 1909 and 1911. In the same period the increase in cattle was 44 per cent. This increase in crops and cattle has been accompanied by an increase in quality, due to the use of improved stock and methods under the supervision of the Government.

AGRICULTURAL EDUCATION.

Agricultural sciences and education (*X. Cong. Internat. Agr. Gand*, 1913, Sect. 2, pp. [412], figs. 3).—This report consists of papers on agricultural science and education, submitted at the meeting of the second section of the Tenth International Congress of Agriculture, previously noted (*E. S. R.*, 29, p. 103).

Annual report on the distribution of grants for agricultural education and research in the year 1912-13 (*Bd. Agr. and Fisheries [London]*, *Ann. Rpt. Agr. Ed. and Research*, 1912-13, pp. XXV+137).—This report contains an account of the reorganization of agricultural education in England and Wales, adapting its administration to the new conditions now prevailing, and the following appendixes: (1) Lists of institutions receiving grants for agricultural education and research in 1912-13; (2) detailed reports on the organization and activities of the College of Agriculture and Horticulture at Holmes Chapel, Midland Agricultural and Dairy College, Kingston, Harris Institute, Preston, E. Anglian Institute of Agriculture, Chelmsford, and the Hampshire Farm School, Basing; (3) notes on work at research institutes; (4) notes on investigations aided by special research grants; (5) research scholarships in agricultural science; (6) staffs of state-aided institutions; (7) student statistics of state-aided institutions; (8) farm schools and farm institutes; (9) agricultural staffs of county councils; and (10) leaflets and journals and other miscellaneous publications of the board issued in 1912.

Information, regulations, instructions, and courses of study relating to agriculture and horticulture in continuation schools, high schools, and collegiate institutes (*Ontario Dept. Ed., Agr. Ed. Circ. 13 (1) (1913)*, pp. 15).—The plan under which the department of education of the Province of Ontario is cooperating with the department of agriculture to encourage instruction in

agriculture and horticulture in continuation and high schools and collegiate institutes is explained in detail. The instruction will be optional, under the supervision of the director of agricultural education, and will be given by teachers of science holding an intermediate certificate in agriculture and horticulture granted upon the satisfactory completion of two 5-weeks summer sessions at the Ontario Agricultural College, or by the district agricultural representatives. A board of trustees that provides and maintains satisfactorily a course in agriculture and horticulture in the lower school of the high school course extending over 2 years, including pupils' home projects under a certificated teacher, will receive \$100 and the teacher \$75. To the school board which, in addition to the home projects, provides and maintains experimental and demonstration plats at or in connection with the school for the practical instruction of the pupils, an additional grant not to exceed \$25 will be paid, and to the teacher an additional annual grant of \$25. When the work is conducted by a county agricultural representative he will be paid the grants specified for the teacher. The 2-year middle school course may be taken only in schools where the lower school course is being taken. The same grants will be paid and the same requirements as regards instruction and examinations made as in the lower school course.

The lower school course of study with suggested home projects and the middle school course are outlined. At least 2 hours a week during each of the 2 years of both lower and middle courses are to be devoted to this work.

Information, regulations, instructions, and course of study in elementary agriculture and horticulture for rural and village public and separate schools (Ontario Dept. Ed., Agr. Ed. Circ. 13, 1913, pp. 18).—The department of education is also cooperating with the department of agriculture of the Province of Ontario in introducing elementary agriculture and horticulture into the rural and village schools. The instruction is optional, under the general supervision of the director of elementary agricultural education, and given by teachers either not especially certificated, or holding special certificates in elementary agriculture and horticulture. These may be obtained on the completion of (1) a 10-weeks spring course at the Ontario Agricultural College, (2) 2 summer sessions at the college and a directed winter's reading course, and (3) a course in agriculture at a high school followed by a further course at the normal school and one summer session at the college. Besides the classroom instruction there will be practical work carried out either as a home gardening plan or as a school gardening plan. A rural or village school board which provides and maintains satisfactorily throughout the year a course in elementary agriculture and horticulture with supervised home gardens or projects and an uncertificated teacher may receive not to exceed \$8 for the trustees and \$15 for the teacher; with a certificated teacher not to exceed \$20 for the trustees and \$38 for the teacher. In addition, where a well-conducted school farm or garden of 6 square rods is maintained the grant may not exceed, with an uncertificated teacher, \$12 to the trustees and \$23 to the teacher; with a certificated teacher, \$30 to the trustees and \$57 to the teacher.

The course of study is outlined.

[Agricultural education in Brazil], P. DE TOLEDO (Relat. Min. Agr. Indus. e Com., Brazil, No. 1 (1912), pp. 5-59, pls. 14).—This is the report for 1912 by the minister of agriculture, industry, and commerce, including among other matters, the organization of agricultural instruction and research at the Higher School of Agriculture and Veterinary Medicine at Rio de Janeiro, 2 secondary or theoretical practical schools of agriculture, 8 agricultural apprentice schools, itinerant agricultural courses, 7 demonstration fields, 2 experiment stations, 2

sericultural stations, 3 zootechnical stations, 2 model breeding farms, a botanical garden, a national museum, and a forest nursery.

A teacher training school in gardening and manual training, E. KATZ (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 25, pp. 367-369).—The author describes a private experiment begun in April, 1913, at the A. and F. Simon institution at Hanover, near Peine, in the training of teachers in gardening and manual training. The instruction is given in 2 half-year courses, comprising in the summer practical gardening 20 hours, woodworking 4, paste work 3, drawing 3, horticulture 4, chemistry 2, physics 2, political economy 2, and pedagogics 4 hours; and in the winter wood and metal work 24 hours, paste work 4, gardening 4, drawing 4, chemistry 2, physics 2, and methods 4 hours. The director is assisted by an experienced horticulturist and manual training instructor. The school has an area of 50 acres, 44 of which are planted to fruits and vegetables grown for profit.

The Massachusetts plan of secondary vocational agricultural education, R. W. STIMSON (*Business America*, 14 (1913), No. 5, pp. 451-457).—The author of this article is carrying out under the direction of the Massachusetts board of education a plan for the development of agricultural training of the grade below that of the college. The plan has a number of unique features. Principally it insists on a division of time about as follows: For the execution of the home projects, including work during vacations and other out-of-school hours, 50 per cent; and for the related study, 30 per cent. The remaining 20 per cent of the time of the boy is devoted to general culture and good citizenship instruction, wherein systematic courses may be provided in such subjects as English, history, civics, current events, and science.

Agricultural education through home projects: The Massachusetts plan, W. T. BAWDEN (*Vocational Ed.*, 3 (1913), No. 2, pp. 86-105, figs. 4).—This article deals with the observations, made by the author, of the work in agricultural education in some of the public high schools of Massachusetts. He considers that although there is a high per capita cost, agricultural education is really an investment, not an expense. The work is deemed practical, and the supervision of unusual efficiency, so that the outlook is encouraging.

Enthusing 20,000 young folks in rural life, E. H. FORBUSH (*New England Homestead*, 68 (1914), No. 1, pp. 3, 4, fig. 1).—This article deals with the growth of the boys' and girls' agricultural club movement in the State of Massachusetts. It is noted that the legislature of 1912 passed a bill appropriating \$200 to each incorporated agricultural society for children's and youth's premiums, and the 1913 legislature appropriated \$1,000 to be expended through the state board of agriculture for the promotion and development of state exhibits and contests.

Sixty lessons in agriculture, B. C. BUFFUM and D. C. DEEVER (*New York, Cincinnati, and Chicago*, [1913], pp. 272, pl. 1, figs. 164).—This book is intended for the sixth, seventh, and eighth grades, and as the treatment is not technical, can be used in schools whose teachers have had no special training in school agriculture. Almost every chapter closes with questions, practical exercises, and references to the farmers' bulletins of the U. S. Department of Agriculture.

A course of study in agriculture for high schools, W. P. EVANS (*Jefferson City, Mo.: State Dept. Ed.*, 1913, pp. 48).—This circular, containing a syllabus of a course in agriculture, lists of required equipment in laboratory and library, and general suggestions to teachers, has been prepared by the state department of education as a means to promote uniformity in equipment and course of study.

Elementary agriculture, W. L. NIDA (*Chicago* [1913], pp. VI+228+VII-XXXV, pl. 1, figs. 109).—This is a book for the fifth and sixth grades. It begins with animal life, describing the different breeds of farm stock and their usefulness, and subsequently takes up how to produce the best crops through the use of fertilizers, tillage, and rotation; how to distinguish between friends and foes in the insect and bird kingdoms; how to engage profitably in dairying, gardening, bee keeping, and poultry raising; and how to preserve the fruits of the harvest for winter use. There are special chapters on farm sanitation and country roads.

School gardening, L. B. HYDE, edited by T. W. SANDERS (*London*, 1913, pp. 104, pl. 1, figs. 68).—This is a simple book for teaching the rudiments of practical horticulture in a clear and concise form in the elementary schools. It gives directions for laying out plats, propagating and cultivating fruits, flowers and vegetables, and indoor school gardening. A series of typical questions on the contents is added.

Textiles—a handbook for the student and the consumer, MARY S. WOOLMAN and ELLEN B. MCGOWAN (*New York*, 1913, pp. XI+428, pl. 1, figs. 137).—This volume, which is intended "as a text-book for college classes or for study clubs and as a guide for the housekeeper or individual consumer of textiles and clothing, the teacher, the club woman, the saleswoman, and as an introductory survey of the subject for the student who contemplates professional work in the textile industries," is based upon the authors' experience in teaching textiles to college students. Such subjects are included as the beginning of the textile industries, spinning and weaving, woolen and worsted (raw materials and manufacture), cotton, silk, linen and minor fibers, consumer's judgment of textiles, microscopic and chemical study of textile fibers, dyeing of textile fibers, laundry notes, hygiene of clothing, some economic and social aspects, and clothing budgets. The volume contains a bibliography and glossary as well as an index.

The training of boys in cooking after leaving school, C. H. SENN (*Jour. Roy. Sanit. Inst.*, 34 (1913), No. 11, pp. 522-526).—The author outlines the qualifications of a chef and states how boys are trained to become cooks in England and France.

MISCELLANEOUS.

Twenty-sixth Annual Report of Indiana Station, 1913 (*Indiana Sta. Rpt.* 1913, pp. 88).—This contains the organization list, reports of the director and heads of departments, the experimental features of which are for the most part abstracted elsewhere in this issue, and a financial statement for the state funds for the fiscal year ended September 30, 1913, and for the remaining funds for the fiscal year ended June 30, 1913.

Twenty-second Annual Report of Oklahoma Station, 1913 (*Oklahoma Sta. Rpt.* 1913, pp. 112, figs. 18).—This contains the organization list, a brief report by the director, a financial statement for the fiscal year ended June 30, 1913, departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue, an article on The Poisoning of Cattle in the Pasture, noted on page 584, and reprints of Bulletin 95, section 2 of Bulletin 99, and Circular 15, all of which have been previously noted.

Twenty-fifth Annual Report of Rhode Island Station, 1912 (*Rhode Island Sta. Rpt.* 1912, pp. 185-241+VI).—This contains the organization list, a report of the director, including meteorological observations and notes on experimental work for the most part abstracted elsewhere in this issue, and a financial statement for the fiscal year ended June 30, 1912.

Twenty-sixth Annual Report of South Carolina Station, 1913 (*South Carolina Sta. Rpt. 1913, pp. 34*).—This contains the organization list, a report of the director on the work of the station, a financial statement for the fiscal year ended June 30, 1913, and departmental reports, of which those of the botanist and entomologist are abstracted elsewhere in this issue.

[**Annual Report of the Rothamsted Experimental Station, 1912**], E. J. RUSSELL (*Rothamsted Expt. Sta., Harpenden, Ann. Rpt. 1912, pp. 26*).—A progress report for the year.

Third report on the work of the Association of Austrian Experiment Stations for the year ended September 30, 1913 (*Ztschr. Landw. Versuchsw. Österr., 16 (1913), No. 10, pp. 985-1002*).—The work of these institutions is briefly summarized.

Agricultural report for Finland, 1911 (*Landtbr. Styr. Meddel. [Finland], No. 85 (1911), pp. 227*).—This report contains accounts of the meteorological and crop conditions in Finland and of the activities of the various state educational and administrative agencies for the advancement of Finnish agriculture during the year. Summarized reports of the agricultural experiment station at Aunä, the agricultural laboratories at Helsingfors, Vasa, and Viborg, and of the seed control stations at Viborg and Björneborg are also included.

The work of the Dominion Experimental Farms, F. T. SHUTT (*Trans. Canad. Inst., 10 (1913), I, No. 23, pp. 17-40*).—An account of the history and work of these farms is given.

The development of the Möckern Experiment Station under the direction of O. Kellner, J. VOLHARD (*Landw. Vers. Stat., 79-80 (1913), pp. 903-922*).—A descriptive account is given.

The annual register of agricultural experiments with full abstracts, 1913, edited by J. W. HURST (*Ann. Reg. Agr. Expts. [London], 1913, pp. 125*).—This publication contains brief résumés of experimental work conducted in England, Scotland, and Ireland. A list of new seeds and plants is appended.

Report of the Conservation Commission of the State of California, 1912 (*Rpt. Conserv. Com. Cal., 1912, pp. VIII+502, pls. 13, figs. 35*).—This is a comprehensive report dealing especially with forestry, irrigation, and the water resources of California. The data pertaining to irrigation have been previously noted (E. S. R., 29, p. 588).

Agricultural laws of Missouri (*Missouri Bd. Agr. Mo. Bul., 11 (1913), No. 5, pp. 35*).—The text of these laws, including those enacted in 1913, is given.

The use of the theory of errors in agriculture and forestry, B. BAULE (*Fühling's Landw. Ztg., 62 (1913), No. 24, pp. 852-866, fig. 1*).—This article deals at some length with methods of estimating the probable errors in experimental work of various kinds in agriculture and forestry.

NOTES.

Hawaii Federal Station.—At the last session of the territorial legislature an appropriation was made available to the station to be used in improving the marketing conditions for local farm produce. The territorial market division was established under its supervision, and while the produce sent in during the first month amounted in value to only \$84, shipments have rapidly increased, amounting in February to \$2,200 and in March to \$4,200. An unusually keen interest is being taken in this experiment. The territorial market makes available a larger market than had ever been open to the local farmer and at considerably better prices. Among the results of its establishment may be noted the greatly increased plantings of miscellaneous farm produce and the extension of poultry and hog raising.

Kansas College and Station.—President H. J. Waters has been granted leave of absence to make an inspection of the bureaus of education and agriculture in the Philippine Islands, and will subsequently visit China, India, Egypt, and other countries, returning about October 1. Dr. J. T. Willard has been designated acting president during this period.

Stanley Clark has been appointed superintendent of the new substation at Colby where wells are being drilled and irrigation and dry-land farming operations being begun. Malcomb C. Sewell, formerly assistant in soils at the Ohio State University, has been appointed superintendent of the Garden City substation. Both appointments became effective March 1.

Kentucky Station.—Dr. L. W. McElyea, of the hog cholera serum administration work, resigned February 1 and has been succeeded by Dr. R. L. Pontius. H. W. Rickey has been appointed poultry expert to organize boys' and girls' poultry clubs. G. C. Routt, assistant in animal husbandry, resigned April 1.

Michigan Station.—Arthur K. Hart has resigned as assistant chemist and has been succeeded by J. H. Torrence, a 1913 graduate of the University of Arkansas.

Nebraska University.—The department of agricultural engineering is to give a 6 weeks' course in steam and gasoline engines and automobiles beginning about June 8. A rural ministers' short course is to be held at the university farm June 11-16.

North Carolina Station.—F. E. Carruth, a graduate of Wesleyan University, has been appointed assistant chemist and has entered upon his duties.

Oregon College and Station.—Dean A. B. Cordley, of the school of agriculture, has been appointed director of the station.

Clemson College and Station.—The extension division has just finished conducting agricultural rallies in 132 public schools in the State. Each of these schools has a 3-acre demonstration plat and is teaching agriculture under the direction of the college.

The station has purchased a pure-bred Percheron stallion and a pure-bred Hereford bull for use with the native stock.

Paul H. Calvin, a graduate in animal husbandry of Purdue University, has been appointed a live stock demonstration agent.

Wisconsin University and Station.—W. H. Strowd, assistant chemist at the North Carolina Station has been appointed chemist in charge of the feed and fertilizer control.

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A short handbook on the carbohydrates, Tollens.....	610
Industrial and manufacturing chemistry: Organic, Martin et al.	610
The ferments and their action, Oppenheimer.....	610
The presence of some benzene derivatives in soils, Shorey.....	610
The mineral elements contained in the casein of milk, Lindet.....	611
The rye flours of commerce and their chemical examination, Hartl.....	612
Unification of the methods of wine analysis.....	612
Report of experimental-chemical and pure yeast laboratory at Klosterneuburg.....	612
Experiments in vinification, Musso.....	612
Crystalline deposits in wines, Mathieu.....	612
Tests in regard to the storage of apple residues.....	612
Further notes on drying potatoes damaged by frost and rot, Rehfeld and Müller.....	613
Significance of potato foliage drying with reference to apparatus, Völtz.....	613
Cassava roots and their by-products, Kling.....	613
American methods of manufacturing preserves, canned foods, etc., Shinkle....	613
Modern cane sirup making, Taggart.....	614
The production of beet sugar in a continental factory, Dowling.....	614

	Page.
Storing of beet chips with lactic acid ferments, Zaitschek.....	614
The fermentation of cacao, Lambert.....	614
Observations on the preparation of cacao, Perrot.....	614
Soap from soy beans, Pontius.....	614
Apocynum or Indian hemp; rubber, Fox.....	614
Determination of nitrogenous constituents in raw rubber, Tschirch and Schmitz.....	615
Industrial hygiene of leather manufacture, Holtzmann.....	615
Preparation of tanning and coloring extracts, Grasser.....	615
The hydrolysis of cellulose, I, Willstätter and Zechmeister.....	615
Some experiments on the conversion of long-leaf pine to paper pulp, Wells.....	615
[Report of the] division of oils and varnishes, Darner.....	616
Oxygen absorption of linseed oil, Darner.....	616
The detection of adulteration in linseed oil, Eldson and Hawley.....	617
Detection of the adulteration of linseed oil, Darner.....	617
Grape-seed oil, Darner.....	617
Tomato-seed oil in Italy, Keena.....	618
The effect of "lime-sulphur" spray manufacture on the eyesight, Weith.....	618
Report of Swiss Agricultural-Chemical Institute at Berne, 1912.....	618

METEOROLOGY—WATER.

The present condition of agricultural meteorology in Brazil, Morez.....	618
[Meteorological observations], Seeley.....	618
Meteorology.....	618
Meteorological summary for the year 1912, Wilson.....	619
On the amount of radioactive products in the atmosphere, Satô.....	619
The soot-and-dust-fall of English towns and cities, Kershaw.....	619
The correlation of rainfall, Peck and Snow.....	619
Rainfall as a determinant of soil moisture, Shreve.....	619
Effect of forests on run-off, Stevens.....	620
Note on the chlorin content of rain water at Tortugas, Fla., Dole.....	620
Water, Wightman.....	620
Ground water and wells, Höfer von Heimhalt.....	620
North Dakota waters, Ladd.....	620
The fertilizing value of sewage and sewage sludge, Clark.....	621

SOILS—FERTILIZERS.

Field experiments and the interpretation of their results, Grégoire.....	621
Proposal for an international uniform classification of soils, Louis.....	621
Composition of the soils of the Sussex area, New Jersey, Blair and Jennings.....	622
Soil analyses, Ince.....	622
The soils of tropical South America, Medina.....	622
The marsh formations on the German North Sea coast, Gruner.....	622
The soils of Uruguay, Puig y Natino.....	623
Determination of the reaction and the basicity of soils, Christensen.....	623
Experiments with water solutions of the soil, Leoncini and Masoni.....	623
Circulation of nitrates in the soil, Malpeaux and Lefort.....	623
Nitrate formation in forest soil, Vogel von Falckenstein.....	624
Rothamsted investigations on production of plant food in the soil, Russell.....	624
Methods for the biochemical study of soil, Stoklasa.....	624
[Soil bacteriological investigations], Van Suchtelen.....	624
Investigations on soil fatigue, Kaserer.....	624
Essentials in the management of California soils, Lipman.....	625
The effect of treating sand soil with moor soil, Krüger.....	625
Gullyng and its prevention, Calhoun.....	625
Green manuring in California, Lipman.....	625
Efficiency of soluble manures in dry years, Léonardon.....	626
Soil nitrogen.—Green-manures.....	626
Nine years' experiments with the new nitrogenous fertilizers, Rhodin.....	626
The nitrate position and results.....	626
Phosphate deposits in southwestern Virginia, Stose.....	626
The use of lime and gypsum on California soils, Lipman.....	627
New fertilizers, Zolla.....	627
The influence of catalytic substances, Rivière and Bailhache.....	627
Sulphur and iron pyrites as fertilizers, Vermorel and Danthony.....	627

EXPERIMENT STATION RECORD.

VOL. XXX.

MAY, 1914.

No. 7.

No better evidence is needed of the place which agricultural education has attained in the public mind than the passage by Congress of the extension measure signed by the President on May 8. It will be recognized as a highly significant step in the advancement of the great national industry through the aid of the General Government, rounding out and completing the movement inaugurated in 1862 with the passage of the land-grant act for the establishment of agricultural colleges. Since that radical step was taken, which settled the right of the Federal Government to aid education in the States, the national attitude toward direct appropriations for agriculture has undergone a complete change.

This new measure is the sixth act which recognizes agriculture as an appropriate subject for promotion by the Federal Government, and the fifth to provide permanent grants from the public Treasury to be used through the system of state institutions established by the Morrill land-grant of 1862. If the recognition of agriculture as a subject for national aid and attention has seemed tardy, it has been none the less emphatic, and in this last instance it represents a far wider expression of favor than any previous measure of the sort. The welfare of agriculture, even to the point of considering the individual farmer and farm home, has become a matter of national concern, limited by no state boundaries.

The passage of the Extension Act was a response to a widespread public demand, more so than any of the previous acts. Advocacy of it came not alone from a group of educational institutions which conceived the plan and would be the beneficiaries under it; but in an unusual degree it came as an intelligent expression of farmers through their organizations, and from the various agencies which stand close to them, such as the bankers and the railroads, commercial clubs and related bodies, and welfare organizations generally. It thus expresses, probably more emphatically than any previous national action, the very general realization of the fundamental relation of agriculture and of the people living under it to the welfare and prosperity of the whole country. Else, why should the nation

bind itself to an annual appropriation which will soon reach beyond \$4,500,000, and the States in accepting it agree to practically duplicate the amount for a like purpose? It is not a sop to the farmers. It is the mature expression of a national policy. It is for the improvement of the country's greatest industry, that the national resources may be made more productive and conserved for the benefit of posterity.

The Smith-Lever Act, as the extension measure just enacted seems destined to be known, completes a campaign of education extending over several years. Its inception may perhaps be traced to the report of a committee on extension work of the Association of American Agricultural Colleges and Experiment Stations in 1906. This committee, as the result of an inquiry into the status of agricultural extension teaching, found three hundred and seventeen agencies, including thirty-eight agricultural colleges and experiment stations, then engaged in some form of extension work, mainly farmers' institutes. It recommended that each agricultural college organize as soon as practicable a department in extension teaching in agriculture, coordinate with other departments or divisions.

This recommendation was repeated in 1907 and 1908, and in the latter year the committee also advocated "that the Association place itself on record in favor of a moderate federal appropriation to be made to the land-grant colleges for the purpose of carrying on extension work in agriculture under a plan which requires the States also to make appropriations for the work."

At the Portland meeting of the Association in 1909, the same committee reported a detailed plan for federal aid. This plan included an annual appropriation of \$10,000 to the land-grant college of each State and Territory for extension work in agriculture, domestic science, and other phases of rural life. This initial appropriation was to be supplemented after two years by annual grants, equal to those made by the respective state legislatures, but not to exceed one cent per capita of the total population of the State or Territory.

A bill embodying these ideas was introduced into the House of Representatives December 15, 1909, by Hon. J. C. McLaughlin of Michigan. No action was taken on this measure in either House of Congress, although in the following June a bill providing for co-operation with the States in vocational education was favorably reported from the Senate Committee on Agriculture and Forestry, in which an appropriation was included for extension departments in the land-grant colleges under a plan differing from the McLaughlin Bill in numerous important details.

Meanwhile, the extension idea was widely propagated and found many advocates among public men. Demonstration work had been

organized in the South, several States largely developed their activities in extension, an organization of business interests was formed to promote national legislation, and private funds began to be contributed for conducting extension campaigns among farmers through meetings and demonstrations. The agencies multiplied and the sentiment for such a nation-wide movement developed with marked rapidity. The exploitation of the work of the experiment stations, their disclosures of the inefficient, uneconomic and wasteful practices often followed, and the presentation of statistics of farm conditions, enforced the conviction that agriculture was not keeping pace with modern progress and that added means were indispensable for reaching and influencing the mass of farmers on the land.

The opening of the Sixty-second Congress brought a number of bills proposing aid for extension work. Among these was the Lever Bill, introduced by Hon. A. F. Lever of South Carolina, June 12, 1911, and the McKinley Bill, introduced by Hon. W. B. McKinley of Illinois, August 10. Subsequently the Smith-Lever Bill was drawn up and introduced by Hon. Hoke Smith of Georgia into the Senate and by Mr. Lever into the House in January, 1912. This measure was eventually modified in some respects and passed by the House in August. It came before the Senate in December, but on January 31, 1913, after extended consideration, that body substituted for it a much more comprehensive bill for vocational education and no agreement was reached between the two Houses before adjournment.

Substantially the original Smith-Lever Bill was reintroduced into the Sixty-third Congress April 7, 1913, and on September 6, its sponsors so modified its provisions as to provide for cooperative extension work between the agricultural colleges and this Department. This measure, with some further amendments, passed the House January 19, 1914, and the Senate February 7. After several months in conference the report of the conferees was agreed to, and on May 8, as previously stated, it received the signature of President Wilson. It goes into effect, therefore, on July 1, 1914, less than five years from the time the movement for such a measure was inaugurated in Congress.

In its final form the Act provides that "in order to aid in diffusing among the people of the United States useful and practical information on subjects relating to agriculture and home economics and to encourage the application of the same," there may be inaugurated in connection with the colleges receiving federal aid under the Morrill acts, agricultural extension work to be carried on in cooperation with this Department. This work is to consist of "the giving of instruction and practical demonstrations in agriculture and home economics to persons not attending or resident in said colleges in the several

communities, and imparting to such persons information on said subjects through field demonstrations, publications, and otherwise."

For the maintenance of the work there is permanently appropriated \$480,000 per annum, or \$10,000 for each State which accepts the provisions of the Act. In addition, there is appropriated \$600,000 for the second fiscal year of its operation, and for each year thereafter for seven years \$500,000 additional, until a total of \$4,100,000 is reached, which with the \$480,000 makes a total of \$4,580,000, and continues as a permanent annual appropriation. Unlike the initial appropriation of \$480,000, these additional appropriations are to be allotted annually to each State by the Secretary of Agriculture in the proportion which its rural population bears to the total rural population. They are also conditional upon the provision by the States of an equal sum for maintenance of the work, supplied either by direct appropriation, or contributions from the county, college, or local authorities, or from individuals within the State.

The Act further provides that the extension work authorized is to be carried on in such manner as may be mutually agreed upon by the Secretary of Agriculture and the colleges. Before the funds appropriated become available, plans for the work must be submitted to the Secretary and receive his approval.

In its provisions as to care of funds, etc., the Act follows in a general way the language of previous legislation for the agricultural colleges and experiment stations. It is specified that in States where there are two or more colleges receiving the benefits of the Morrill acts, the legislatures shall designate the institutions to receive the appropriations. No part of the appropriation can be used in the purchase, erection, or repair of buildings, the purchase or rental of land, college course teaching, promoting agricultural trains, or other purposes not specifically authorized, and not more than five per cent for the printing and distribution of publications. Payments from the federal Treasury are to be made semiannually on January 1 and July 1, and a financial report thereon must be submitted prior to September 1. A full report of operations under the Act is also required prior to January 1 from the several colleges, while the Secretary of Agriculture in turn must make an annual report to Congress.

In one respect the measure is unusually broad as compared with the legislation which preceded it. In addition to the assistance given specifically to agriculture, it recognizes the home and home maker, and the general conditions of country living. It is probably the first federal legislation to be adopted in which the term "home economics" formally appears. It is, therefore, a recognition not only of the American farmer but of the American home maker and of the worth and dignity of the vocations which they represent.

It will be noted that the Extension Act provides for cooperative action between the General Government and the States, between the Federal Department of Agriculture as representing one agency and the agricultural colleges as representing the other. For the pressure for extension activities has not been confined to the colleges in the States, but has been felt in increasing degree by the Department of Agriculture at Washington, and Congress has seen fit to appropriate moneys for demonstration work to be used in the States through the Department.

The Department and the colleges, with their experiment stations, constitute the two great agencies for acquiring agricultural information. There are many minor contributory agencies which are not to be overlooked, but they are independent and incidental rather than primary. The Department, working on broad lines and problems, frequently not bounded by a State but regional, works out matters which it is desirable to get before the people, or leads up to a campaign which it is in the interest of the States to have conducted. The individual stations likewise make discoveries which are of both state and regional application, and they also work out details for local conditions, sometimes covering an entire State, sometimes much more restricted.

These results and applications, whatever their source, deserve to be brought to the attention of the public, and this makes desirable some organized action. The new extension measure provides the colleges with the means for this and also provides for cooperation. The funds carried in the Smith-Lever Act are not appropriated directly to the Department of Agriculture as its funds to dispense among the States, and they are not given to the States unconditionally. They are designed "to provide for cooperative agricultural extension work between the agricultural colleges in the several States . . . and the United States Department of Agriculture." The Department receives no portion of the funds appropriated under the Extension Act, but these are paid semiannually to the state authorities on the warrant of the Secretary of Agriculture, who is charged with the proper administration of the law. The plan of organization at the colleges contemplates the establishment of extension divisions at each of the colleges. Into these all the extension funds and work will be grouped, just as those for experimentation and research are grouped in the experiment stations. These extension divisions are state organizations and not federal, and the funds supplied under the new act become the funds of the designated college, subject to certain conditions and to a measure of federal control.

On the other hand, the Department has separate funds appropriated to it by Congress for extension (demonstration) work to be con-

ducted in the States. The most conspicuous examples are those for the cooperative demonstration work in the South which originally grew out of the ravages of the boll weevil, and demonstration work in the northern States which was an offshoot of the farm management studies. These two funds, together with other contributions to be used with them, amount to approximately \$800,000. In addition there are other funds, portions of special appropriations, which are employed in demonstration and extension activities.

Heretofore the Department's demonstration work has been conducted in part independently of the agricultural colleges. No uniform plan has been followed, and the varied activities in extension lines have not been definitely brought together and administered through one departmental agency. Such an administrative agency has now been established, through a States Relations Committee, and to it will also be assigned the general administration and supervision of the new extension fund under the Smith-Lever Act. There will thus be for the first time a single central agency in the Department which will deal with the extension work of the Department and with the extension divisions of the several colleges. The Department now proposes to make the agricultural colleges state centers of all its demonstration and other extension work, to be conducted in cooperation with the state institution. It will be united in the closest manner feasible with the state activities, so as to secure unity of action under a consolidated state organization. It is felt that such a combining and coordinating of these efforts will materially strengthen the conduct and the effectiveness of the undertaking as a whole.

Cooperation between the Department and the agricultural colleges has been discussed in an abstract way for a long time, and there have been many instances of such cooperation covering a wide range of subjects. There is now, however, an opportunity for cooperation on a national scale along the broad and varied lines of extension work in agriculture and home economics. This should be improved by devising and putting into operation an effective system which, while carefully preserving the autonomy and special responsibilities of each party, will bring the state and federal agencies for the betterment of agriculture and the practical education of the people on our farms into such close and harmonious relations as will best procure the economical and efficient use of the great sums of the people's money devoted to these purposes, and create an American system of extension service for our rural communities more widespread and beneficial in its operation than anything in this line the world has yet known.

To do this it will be the Department's aim to make the system cooperative in the best and most liberal sense,—a joint effort providing for cooperative planning, while entrusting to the extension departments of the colleges the details of execution, in accordance

with project agreements drawn to suit the varied requirements of different lines of work.

The more strictly cooperative work will usually involve only the Department's funds and such part of the Smith-Lever fund or state funds as the colleges may choose to put into the cooperative arrangement. The cooperation under the Smith-Lever Act will simply consist in the submission by the colleges of their projects to the Department for approval in advance, much as are the Adams fund projects, unless the college shall decide to use the Smith-Lever fund in whole or in part on projects which also involve the use of the Department's funds. State funds which the colleges may have for extension work outside the Smith-Lever projects and joint enterprises with the Department will of course be entirely within the control of the colleges, but it is hoped that even these funds will be so used through the Extension Divisions that there will be proper coordination of effort and avoidance of duplication all along the line of the institution's extension activities.

The inauguration of agricultural extension on the present broad basis is a tribute to the native intelligence of the American farmer. It recognizes his readiness for it and his ability to profit by it. A movement along the proposed lines would have been impractical under other conditions. It will aim confidently at putting into practice methods and ideas which are new to him and which require a high degree of intelligence to carry out.

There is a progressiveness in the American farmer and an adaptability when properly aroused which makes possible radical changes requiring a breaking away from tradition and custom. He needs to be shown and convinced, and when his confidence is won he is an apt pupil. He is capable of the highest type of farming, and of carrying out practices in irrigation, in seed improvement, in soil renovation, in dairy sanitation, and in many other lines which it would be useless to attempt to inculcate in the agriculture of many lands.

One very striking and tangible result of the agricultural work of the past quarter century has been the effect on the average American farmer, winning his confidence, broadening his vision, and making him more receptive of new ideas and more ready to change. As a matter of fact, very many radical and widespread changes of practice have already resulted, which have now become so generally accepted that they no longer excite comment except where comparison is presented. This is a remarkable achievement, worth all it has cost, and it has paved the way for the present extension propaganda.

The fear has been expressed that the experiment stations might suffer from the popularity of extension work, that attention would be diverted from them and from the need of their further support.

Instead, this Act gives more definite purpose and force to their work, and emphasizes its necessity in the development of agricultural practice. It is rooted in their activities and will be sustained by them. Without them it would soon suffer the fate of the old-style farmers' institutes.

The new work will make enlarged demands upon the stations and bring them closer to the people. While it may at times overshadow them somewhat in the popular mind, it will add a vast army of workers to their clientele, who will realize their ultimate dependence on experimentation and research, and who will be in closer touch with the people than any similar body of men and women yet organized. They will therefore be in the best position to popularize and advocate the work of the experiment stations.

In thus seeking to promote the general welfare by a comprehensive and permanent system of extension work on the farm and in the home, the Federal Government becomes an active cooperator in the campaign for rural development and progress which has made such remarkable headway within recent years. For it is within a comparatively short period that the responsibilities of American civilization as a whole to the open country have become fully appreciated.

Less than seven years ago, the holding of a conference by the Massachusetts Agricultural College for the momentary bringing together of the varied forces making for rural progress—educational, social, religious, as well as distinctively agricultural—was regarded as a novel and suggestive departure from the prevailing conception of agriculture as an isolated industry and its welfare as a matter of comparatively remote general significance. In 1909, after the holding of similar sectional conferences in New England and elsewhere, the appointment of the National Commission on Country Life and similar related bodies, and the inauguration of some form of extension work in nearly every State, we find the committee on extension work of the Association of American Agricultural Colleges and Experiment Stations reporting that even "the various institutions engaged in work in behalf of our agricultural industry or rural people have labored very much by themselves. There has been a very slight measure of cooperation between rural church, country school, grange, club, agricultural college, and library." Still less, of course, was this cooperation in evidence as between agricultural and nonagricultural organizations.

As an example of the changing point of view in this respect may be cited the conferences on country life development held at Louisville, Kentucky, April 7-10, 1914. These conferences were sponsored by purely educational agencies, constituting the seventeenth annual

session of the conference for education in the South, and were in close cooperation with the Southern Educational Association, while the running expenses were defrayed by the Southern Education Board. The announced purpose of the gathering was not primarily pedagogic, as might have been expected, but to devise ways and means for all who are interested to organize and build up country life in the South. Its scope included conferences for farmers, business men, country women, boys and girls, ministers, physicians, and editors, as well as school workers, on special phases of the problem, together with general sessions in which all the groups met together for the consideration of the manifold matters which were found to be of common interest.

The conferences were noteworthy for emphasis placed upon the demonstration method and the use of illustrative material. Formal organizations for cooperative stock breeding and selling and the marketing of farm products and boys' and girls' clubs were effected from among those present, and programs carried out to show their practical workings. There was a government parcel post exhibit with experts from this Department to give advice as to the possibilities of this new service, the proper packing of goods, and ways and means to realize its full possibilities. The Kentucky State University had on exhibition a model home, equipped with modern conveniences, and offered lectures and demonstrations on home economics and rural sanitation. There was also a country school of modern type, a cooperative creamery, a model poultry plant, and a wealth of similar illustrative material.

None the less, perhaps the most valuable demonstration of all was that of the spirit of cooperation and good will toward agriculture, and the acknowledgment of its predominating importance in national life, manifested by the various and seemingly diverse agencies which shared the labors of the conferences and participated in their benefits. In their conception and development, the Louisville meetings reflected in no small degree the spirit of the times, and go far to explain why state and national governments are undertaking a great, permanent system of agricultural extension work.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A short handbook on the carbohydrates, B. TOLLENS (*Kurzes Handbuch der Kohlenhydrate. Leipsic, 1914, 3. ed., pp. XX+816, figs. 30*).—In this edition of this well-known, authoritative handbook parts 1 and 2 have been combined. The book, while not dealing with everything that has been done in the realm of carbohydrate chemistry, contains the most important data which have accumulated in this field of study, and considers both its scientific and technical aspects.

Industrial and manufacturing chemistry: Organic, G. MARTIN ET AL. (*London, 1913, pp. XX+726, pls. 4, figs. 253*).—This book deals with the methods of manufacture and analysis in use in the following industries: Oil, fat, varnish, soap, wax, enamel, oilcloth, linoleum, milk, butter, cheese, casein, condensed milk and milk powders, margarin, fatty acids and candle-making materials, glycerol, essential oil, synthetic perfume, sugar, glucose, dextrose, invert sugar, honey, starch, dextrin, cellulose, wood and timber preservation, paper making, mercerization, collodion, artificial silk, wine and beer making, spirits and industrial alcohol, vinegar, lactic acid, butyric acid, charcoal and wood-distilling, turpentine and rosin, camphor, industrial gums and resins, rubber, oxalic acid, formic acid, tartaric acid, aldehydes, alcohols, esters and fruit essences, illuminating gas, coal tar and coal-tar products, synthetic coloring matters, natural dyestuffs, ink, paint and pigments, textile fibers, bleaching and water-proofing, dyeing and color-printing, leather and tanning, glue, gelatin, albumin, modern synthetic and other drugs, modern explosives, and photographic chemicals.

The ferments and their action, C. OPPENHEIMER (*Die Fermente und ihre Wirkungen. Leipsic, 1913, 4. rev. ed., vols. 1, pp. VIII+485; 2, pp. VIII+487-1150*).—The previous edition of the first volume has been noted (E. S. R., 22, p. 608). The second volume has been entirely rewritten, and contains an additional chapter, of 158 pages, on the physical chemistry of enzymes and enzym action, by R. O. Herzog.

The presence of some benzene derivatives in soils, E. C. SHOREY (*U. S. Dept. Agr., Jour. Agr. Research, 1 (1914), No. 5, pp. 357-363*).—Three aromatic compounds, namely, benzoic acid, metaoxytoluic acid, and vanillin, were isolated from samples of sandy Florida soils. The soils were composed of quartz sand ranging in color from light gray to brown, contained very little organic matter, and were devoted to orange culture. The organic matter is deposited as a thin layer on the grains of sand, and if the soil is treated with dilute alkali, it is dissolved away and pure white quartz sand remains.

Benzoic acid was isolated from a subsoil and there were no indications to show that it might be present in the corresponding surface soil. Metaoxytoluic acid was obtained in quantity only from subsoils. "The compound ob-

tained from the soil has the properties of metaoxytoluic acid, with the carboxyl, hydroxyl, and methyl radicals in the 1. 3. 5. positions, respectively. . . . Metaoxytoluic acid was made from sulphotoluic acid according to the method of Jacobsen, and its properties were compared with the compound obtained from the soil, the two agreeing in every respect." Vanillin was isolated and the amount present, as noted by the Folin and Denis method (E. S. R., 28, p. 807), was determined. "Sample No. 1 gave 0.001 per cent of vanillin, or 10 parts per million, while sample No. 2 showed 0.00048 per cent, or 4.8 parts per million."

In some previous work (E. S. R., 24, p. 524) it was shown that the methoxyl radical was present in many soils and could be determined by the Zeisel method. "A determination of the methoxyl in samples Nos. 1 and 2 by this method gave, for sample No. 1, 0.065 per cent of methoxyl calculated to vanillin, and for sample No. 2, 0.05 per cent." As the quantity of vanillin calculated was very much in excess of that isolated from an alkaline extract or that indicated by the Folin and Denis method it is probable that a considerable portion of it originates from compounds other than vanillin.

Of the three substances isolated, only benzoic acid and vanillin are naturally occurring products. The three substances, however, may be derived from, or transformed into one another. The preparation of metaoxytoluic acid in the laboratory does not suggest any process by which it may be formed in the soil from plant products or other compounds known to occur in soils. "Using the maximum figures for quantities obtained in these investigations and calculating to the acre-foot of soil, the following approximate quantities are obtained: Benzoic acid, 350 lbs.; metaoxytoluic acid, 800 lbs.; and vanillin, 40 lbs. to the acre-foot. In the case of the two acids the method involved considerable loss of material and the actual quantity present in the soil is undoubtedly in excess of these figures.

"The question as to the form in which these compounds exist in the soil is one deserving some consideration, although one not easily answered satisfactorily. It is true of most organic compounds that have been obtained from soils through extraction with dilute alkali that they are not readily obtained as such by water extraction of the soil. In many soils this can be explained, in part at least, by the fact that much of the organic matter in soils is of a resinous nature wholly insoluble in water, and compounds which when separated are easily soluble in water are so incased or protected by the resinous or varnishlike coating effected by this resinous material that they are very slowly dissolved, if at all, when the soil is leached. This effect is quite apart from any absorptive effect and is quite marked in extreme types, such as the sands of Florida and some peats, where either fine grinding or previous treatment with alcohol will render soluble in water organic material that before this treatment was so little soluble as to escape notice."

The methods utilized in the study are given in detail and are discussed.

The mineral elements contained in the casein of milk, L. LINDET (*Orig. Commun.* 8. *Internat. Cong. Appl. Chem.* [Washington and New York], 19 (1912), *Sect. VIII*d, pp. 199-207; *Compt. Rend. Acad. Sci.* [Paris], 155 (1912), No. 19, pp. 923, 924; *abs. in Zentbl. Biochem. u. Biophys.*, 14 (1913), No. 17-18, p. 615).—In this paper it is shown that only about half of the phosphorus contained in casein and obtained by precipitation with rennet is present as a calcium phosphate (probably a tricalcium phosphate), and that the remainder is present as a phosphoric acid compound of casein which is easily hydrolyzed with an alkali. Three-fifths of the calcium is bound to the phosphoric acid and the remaining two-fifths to the casein.

The rye flours of commerce and their chemical examination, K. HARTL (*Kísérlet. Közlem.*, 16 (1913), No. 5, pp. 613-638).—The need for standards in Hungary for rye flour such as exist for wheat is pointed out. A modified Weender crude fiber method is described and a comparative study with it and other methods is recommended, especially with brans and feeding stuffs. As the commercial value of wheat and rye flours rises with the whiteness of these flours, it is recommended that the pekarization test and ash determinations be made for grading the flours, and that in critical cases the degree of fineness be estimated according to the method described.

Unification of the methods of wine analysis (*Informateur*, 5 (1912), No. 43, pp. 262-266; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 8, pp. 1866-1868).—This states the results of a meeting of the International Committee of the Trade in Wine, Ciders, Spirits, and Liquors held for the purpose of obtaining uniform methods of analysis.

Report of the experimental-chemical and pure yeast laboratory of the Royal Institute for Wine Manufacture and Fruit Culture at Klosterneuburg (*Programm u. Jahresber. K. K. Höh. Lehranst. Wein u. Obstbau Klosterneuburg*, 1912-13, pp. 103-159).—A description of the work done by this laboratory during the year 1912, including the results of analyzing grape and other fruit wines prepared by various procedures; notes on the changes taking place during the fermentation of wine, the use of pure culture yeast for fermenting must from grapes infected with fungi, the refermentation of wines, and the effect of pure nitrogen, chloroform, and mustard oil on must and wine; and a comparative study of the Barth and Haas and Halenke and Möslinger methods for determining tartaric acid in the absence and presence of citric acid, decolorizing tests, etc.

Experiments in vinification, L. A. MUSSO (*Agr. Gaz. N. S. Wales*, 24 (1913), No. 5, pp. 407-415, pls. 3).—The purpose of these experiments was to find out (1) "at what stage, at what intervals, and in what quantity sulphurous acid is required to prevent the temperature of the must rising above the critical point; (2) to ascertain the effects of the addition of tartaric acid in various proportions to the must prior to fermentation; and (3) to ascertain the effects of the treatment with sulphurous acid conjointly with the addition of tartaric acid. . . .

"In using sulphurous acid for the purpose of checking the rapidity with which fermentation tends to take place, very good results can be obtained by adding an amount of 7 to 8 oz. of potassium metabisulphite per 200 gal. of must at the moment at which, fermentation having already started, there is a tendency to an excessive rise in temperature. The temperature of the must at the beginning should be a guide for the vine grower; the higher the initial temperature the sooner the metabisulphite should be added to the must."

Tartaric acid had no delaying influence on the fermentation itself, which is contrary to some other experiments which were conducted by the author on a small scale. It probably has the property of stimulating the activity of the yeast and offsetting particularly the retarding effect of sulphurous acid.

Crystalline deposits in wines, L. MATHIEU (*Jour. Agr. Prat.*, n. ser., 25 (1913), No. 8, pp. 240, 241).—This deals with the deposition of cream of tartar, especially by wines which were cooled and stored. Precipitation can also take place during the fermentation process, and a deposit of this substance in wine does not indicate that the wine has been treated with tartrates.

Tests in regard to the storage of apple residues (*Ber. Grossh. Bad. Landw. Vers. Anst. Augustenb.*, 1912, pp. 80, 81).—A study was made of the Scheurlen method, which consists of pressing the fruit residues in casks and interposing a layer of salt between each stratum when it attains a size of 20

to 30 cm. In the experiments two of the casks received no additions of salt, another received 2 per cent of salt, and another 3 per cent. After storage for about 2 months samples were withdrawn from each and the alcohol and volatile acids determined.

The casks with no salt showed, respectively, 2.13 and 2.18 per cent of alcohol and 0.08 and 0.05 per cent of volatile acids calculated on the basis of the fresh substance; the cask with 2 per cent of salt 3.47 per cent alcohol and 0.08 per cent acid; and the cask with 3 per cent of salt 2.93 per cent alcohol and 0.12 per cent acid. The losses in dry substance were very variable and no definite conclusion could be drawn. Drying the residue seems to be a better procedure for conserving it.

These products were relished by steers and swine, but it is recommended that only small amounts be fed at a time on account of the high alcohol content.

Some further notes in regard to the drying of potatoes damaged by frost and rot, REHFELD and MÜLLER (*Jahrb. Ver. Spiritus Fabrik. Deut.*, 13 (1913), pp. 437-466; *abs. in Chem. Ztg.*, 37 (1913), No. 34, p. 346).—In working up potatoes of this character it was found that the efficiency of the drying machinery was 30 per cent lower than usual. Difficulties were experienced in maintaining proper temperatures because of certain chemical changes in the carbohydrate material. Potatoes which came directly from the field were more easily worked than stored potatoes. One of the most disturbing factors was dirt, of which the amount contained in this class of goods was from 32 to 34 per cent. More fuel was necessary for drying this kind of material.

The significance of potato foliage drying with reference to the installation of potato-drying apparatus, VÖLTZ (*Jahrb. Ver. Spiritus Fabrik. Deut.*, 13 (1913), pp. 466-487; *abs. in Chem. Ztg.*, 37 (1913), No. 34, p. 346).—Feeding (balance) experiments were conducted by the author and his associates with sheep on the foliage of two varieties of potatoes.

The results show that potato foliage from the standpoint of nutritive value can be closely compared with good meadow hay. The digestibility of the potato berry was somewhat less than the foliage but toxic effects were never noted.

As the feed value of the potato leaf is high, it is believed that artificial drying by appropriate apparatus is both feasible and profitable, although when favorable weather exists open-air drying can also be used. Storing by pickling (Einsäuerung) involves a loss of about 40 per cent of the organic digestible material and about 12 per cent of crude protein. Some of the nitrogen-containing substances are transformed into sodium nitrate but this salt is of no value for feeding Herbivora.

Cassava roots and their by-products, M. KLING (*Landw. Vers. Stat.*, 82 (1913), No. 3-4, pp. 211-236).—Fresh cassava roots, when shipped, spoil very easily. This results in a blackening of the roots, and consequently they lose their value as a raw material for preparing the tapioca flour used for human consumption. When the tapioca factory is not in a locality where the roots are grown, the fresh roots, after being washed and sometimes peeled, are dried in the sun. The material prepared in this manner can not be used for the manufacture of the usual tapioca starch flour but it can be made into flour which can be used for other technical purposes. Certain firms which work up *Manihot utilissima* by two methods, wet and dry, sell the by-products as starch feed meal, feed meal, and starch slops.

This article gives the results of comparatively complete analyses of these and similar products, compares the figures obtained with pressed potatoes, and discusses their value for feeding stock.

American commercial methods of manufacturing preserves, pickles, canned foods, etc., C. A. SHINKLE (*Menominee, Mich.*, 1912, rev. ed., pp. 221,

figs. 16).—This is a detailed description of methods for preparing conserved or canned goods. The first portion of the book is devoted to the making of pickles, sauces, and vinegars; the second to preserves, jams, jellies, fruit butters, etc., and the equipment required therefor; and the third to the actual processes as carried out in the canneries. A final section is devoted to the cost of producing canned goods. Some illustrations of machinery are shown.

Modern cane sirup making, W. G. TAGGART (*La. Planter*, 50 (1913), No. 10, pp. 160, 161).—A discussion of the factors which go to make up a good cane sirup.

“Clarification is without doubt the most important factor influencing the quality of sirups, and good clarification can only be produced by the use of sulphur and lime. . . . There are two other chemicals, phosphoric acid and hydrosulphites, which are more or less used to aid lime and sulphur in the process of clarification. . . . Rust is very often to blame for the poor grade of sirup which is turned out during the first few days of a campaign. All iron open kettles or evaporators in which sirup is to be boiled should be kept thoroughly enameled. Sirup boiled in contact with iron becomes dark and will not command a good price.”

The production of beet sugar in a continental factory, R. N. DOWLING (*Jour. Bd. Agr. [London]*, 18 (1912), No. 12, pp. 1005–1014, pls. 2).—This is a description of the methods prevailing on the European continent and deals with delivery, weighing, and sampling of beet roots, the disposal of the roots at the factory, washing, weighing, the extraction of the sugar by the diffusion process, purification of the beet juice, waste waters, the “Steffen” process, heat in the factory, labor, and cost of working and delivering beet roots per ton.

Storing of beet chips with lactic acid ferments, A. ZAITSCHEK (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 42 (1913), No. 1, pp. 1–8; *abs. in Chem. Ztg.*, 37 (1913), No. 29, *Repert.*, p. 134).—Carefully pressed and stored chips treated with so-called “Lactopulpe” (A. Moser’s Vindobonapulpe), were found to keep well until the following summer, and with a loss of only 20 per cent of dry substance. The material is considered a good feed for dairy cattle.

The fermentation of cacao, G. LAMBERT (*Bul. Sci. Pharmacol.*, 18 (1911), No. 10, pp. 574–587; *abs. in Chem. Zentbl.*, 1912, I, No. 20, p. 1632; *Jour. Chem. Soc. [London]*, 102 (1912), No. 600, II, p. 972).—The fermentation of cacao is ascribed to *Saccharomyces theobromæ*, which results in a production of alcohol. An oxidation of the coloring matter by theobromase, which is always found in the seed, takes place simultaneously.

Observations on the preparation of cacao, E. PERROT (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 18, pp. 1394–1396).—Cacao beans when subjected to fermentation in order to remove the hulls undergo several changes which result in a variable product and some losses. During the process heat is developed and certain enzymes act upon the tannin compounds, resulting in the production of a brown color. To prevent this lack of uniformity the author recommends sterilizing the cacao beans and suggests removing the hulls by subjecting the beans to the action of a dilute solution of alkali.

Soap from soy beans, A. W. PONTIUS (*Daily Cons. and Trade Rpts. [U. S.]*, 15 (1912), No. 107, p. 494; *abs. in Chem. Ztg.*, 37 (1913), No. 62, *Repert.*, p. 285).—The author states that soy-bean oil can to a certain extent be substituted for coconut oil and cacao butter, but that it must undergo a process of refining before it can be employed for this purpose.

Apocynum or Indian hemp; rubber, C. P. FOX (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 5, pp. 387, 388).—The possibilities of obtaining rubber from the Indian hemp plant are considered. Analytical data are included.

Determination of nitrogenous constituents in raw rubber, A. TSCHIRCH and W. SCHMITZ (*Gummi Ztg.*, 26 (1912), No. 52, pp. 2079–2081; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 21, p. 1042).—As a solvent for rubber pentachloroethan (boiling point 159° C.), tetrachloroethan, and perchloroethylen are recommended.

“Two and five-tenth gm. of raw Para (not washed or deresinified) was dried for eight days in vacuo and placed in a 500 cc. Erlenmeyer flask with 40 to 60 cc. of pentachloroethan; cotton wool was placed in the neck. The flask was heated for 4 to 6 hours at 80° C. till all the rubber had dissolved. After cooling, the liquid was highly diluted with chloroform (about 400 cc.) and allowed to settle in a separating funnel. The precipitate was collected on an ordinary paper filter. Warning is given as to the use of a centrifuge. The residue on the filter was extracted with chloroform in a Soxhlet apparatus, dried in vacuo and weighed. The nitrogen was then determined by the Kjeldahl method. The protein contained 12 to 14 per cent of nitrogen. Ray Para contained 2.9 to 3.1 per cent of residue (11 to 12.6 per cent of nitrogen). Nearly all this nitrogen was found in the insoluble residue, in which, allowing for ash, the nitrogen was from 14 to 15.6 per cent. Preliminary experiments on the nature of the protein are described; it does not appear to be a true protein.”

Industrial hygiene of leather manufacture, with especial reference to the industry in Baden, F. HOLTZMANN (*Gewerbehygiene der Lederfabrikation mit besonderer Berücksichtigung der badischen Industrie. Inaug. Diss., Tech. Hochsch. Karlsruhe*, 1912, pp. 28).—This discusses the various stages of leather manufacture, their significance from a hygienic standpoint, anthrax in tanneries, and the healthfulness of leather workers in general. A bibliography comprising 34 titles is appended.

Preparation of tanning and coloring extracts, G. GRASSER (*Chem. Ztg.*, 37 (1913), No. 37, pp. 373–375).—This gives a short description of the technical processes used for preparing tanbark extracts and commercial vegetable coloring matters.

The hydrolysis of cellulose, I. R. WILLSTÄTTER and L. ZECHMEISTER (*Ber. Deut. Chem. Gesell.*, 46 (1913), No. 11, pp. 2401–2412, fig. 1; *abs. in Nature [London]*, 92 (1913), No. 2291, pp. 107, 108).—This is carried out by treating the cellulose with cold, fuming hydrochloric acid of a specific gravity of 1.204 to 1.212 and which contains from 40 to 41.4 per cent of hydrogen chlorid. The cellulose (cotton or filter paper), after being treated, will show within 24 to 48 hours a conversion of about 95 to 96 per cent of the theoretical quantity of dextrose. Ordinary hydrochloric acid, which contains only 37.6 per cent of hydrogen chlorid, does not decompose cellulose to this extent but merely disintegrates the fiber and causes gelatinization.

“One of the most striking observations recorded in the paper is the very high specific rotation shown by dextrose when dissolved in concentrated hydrochloric acid. In 41.4 per cent hydrochloric acid $[\alpha]_D^{16}$ at 16° C. was found to be 106°, which approximates to that of the so-called α form of dextrose (110°), the ordinary value observed in aqueous solution for the equilibrium mixture of α and β forms being 52.5°. In 44.5 per cent hydrochloric acid, however, the extraordinarily high value of 164.6° was observed for $[\alpha]_D^{16}$ at 5° C.”

Some experiments on the conversion of long-leaf pine to paper pulp by the soda and sulphate processes, S. D. WELLS (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 11, pp. 906, 907; *abs. in Science, n. ser.*, 38 (1913), No. 985, p. 710).—One hundred and fifty small batches were made in autoclaves for the purpose of studying various factors relative to the cooking process in the sulphate method. “It was found that the more caustic soda or sodium sulphid in use, the greater the concentration, the higher the temperature and the longer

the time of cooking, the lower the yields of pulp, and the lighter and easier to bleach. Caustic soda had twice the reducing power possessed by sodium sulphid."

The 19 semicommercial cooks made gave a yield of pulp corresponding to 49 per cent of the dry weight of the wood. The paper made from the pulp was stronger and tougher than the kind usually imported known as "kraft paper." The paper made from the soda pulps of the same wood were not so strong and the yield was less.

[Report of the] division of oils and varnishes, R. W. DARNER (*North Dakota Sta. Rpt. 1912, pt. 3, pp. 484-490*).—This report presents analyses of linseed oils and turpentines and data as to Chinese wood oil and lumbang oil.

Some of the linseed oils were found adulterated with mineral oil. The turpentine oils examined all seemed uniformly adulterated with from 15 to 20 per cent of a light mineral oil. Analyses of two pure samples of Chinese wood oil are reported and the chemical and physical data compared with commercial samples. They agreed well so far as specific gravity, refractive index, saponification number, and unsaponifiable matter were concerned but disagreed in the iodine number which ran higher in the commercial samples.

"The Bacon heat test was applied [to the pure samples] and a good solid 'go back' was obtained in each case. Where the test was applied to the commercial samples only one was found that responded to the test, and that gave a rather pasty solid. On inquiring into the history of these oils as to their usefulness in varnish and paint making, it was found that each sample filled the requirements. This would tend to show that while Bacon's test will indicate purity of some samples, yet it does not indicate the usefulness of the sample in paint and varnish manufacturing."

A heat test was also used, with which each of the samples responded with good "go backs." In this, 20 minutes was taken to bring 100 gm. of oil to 225° C., at which temperature it was held for 20 minutes; 10 minutes was then taken to raise the oil to between 270 and 280° where it was held for 8½ minutes.

This method has the advantage over Bacon's method in that the oil is held for 20 minutes at the same temperature used in varnish making. It also determines whether the oil darkens or changes in viscosity, which is of the utmost importance to the varnish maker.

The data with reference to lumbang oil has been previously reported (E. S. R., 29, p. 811) with the exception of an additional sample of oil obtained from other sources. This differed from those previously reported in the high saponification number and specific gravity.

Oxygen absorption of linseed oil, R. W. DARNER (*North Dakota Sta. Spec. Bul., 3 (1914), No. 1, pp. 8-11, fig. 1*).—It is pointed out that in only one of the experiments cited in the literature quoted was the light factor considered, and in none was the effect of moisture, which has been proved to have a great effect upon the drying of oil and paint films, noted. "This work was undertaken to see if under conditions that would be easily controlled all pure linseed oils would dry in about the same time. The drying tests were made in a glass case 12 in. high, 12 in. wide, and 24 in. long. This case sat on a base containing a mercury seal, so that the case was air-tight and at the same time could easily be lifted and the drying plates taken out and weighed.

"The air was first dried before being drawn through the case by a train of sulphuric acid and calcium chlorid tubes and then warmed to 25° C. by being drawn through a glass spiral tube surrounded with warm water. The humidity within the box was kept constant by exposing a No. 2 beaker containing water. The temperature within the box never varied more than 0.5° from 25°. Light was supplied by two 240 watt tungsten lamps provided with reflectors. The

oil was dried on both glass and aluminum plates 4 by 7 in. in size, with a surface ruled off for drying 3 by 6 in., giving an area of 18 sq. in. for spreading oil for drying; 0.187 gm. of oil was spread out on this surface, giving a uniform thickness of film of approximately $\frac{1}{1500}$ of an inch. Air was drawn into the box at an average rate of one-half liter per minute." The apparatus used is illustrated.

"From the results it may be seen that with the conditions named in these experiments raw linseed oils reach their maximum gain in drying very close around 80 hours and boiled oils around 24 hours. Also 10 per cent adulteration of raw linseed oil by rosin, soy-bean, and other semidrying oils may be detected, as their presence retards the time of drying of linseed oil by a good margin."

The detection of adulteration in linseed oil, G. D. ELSDON and H. HAWLEY (*Analyst*, 38 (1913), No. 442, pp. 3-7, fig. 1).—It was found that a close relation existed between the iodine number and the quantity of ether extract obtained from a partially dried linseed oil. This is especially noticeable when the iodine number and the extract are plotted against one another. The amount of ether extract from linseed oils dried for 2 hours (10 samples) varied from 14 to 19 per cent and the iodine value from 176 to 192.

Linseed oils containing 20 per cent of either colza, whale, cotton-seed, or seal oil gave iodine values which varied from 176 to 185 and ether extracts from 10.4 to 31.6.

"The following equation has been calculated from the curve for the maximum extract of a linseed oil. If I is the iodine value, then the maximum permissible extract for that oil is— $\text{Extract} = 81.9 - 0.35 I$.

"It is suggested that the routine examination of linseed oils be restricted to the determination of the iodine value and the extract as described above, by which means decisive information as to the purity or otherwise of any sample may be obtained."

Detection of the adulteration of linseed oil, R. W. DARNER (*North Dakota Sta. Spec. Bul.*, 2 (1913), No. 21, pp. 369, 370, fig. 1).—This is an application of the method described in the abstract above to the detection of soy-bean oil and other semidrying oils in linseed oil. Five samples of linseed oil examined by the method showed extreme values for the ether extracts from 14.34 to 18 per cent.

Soy-bean oil with an iodine value of 132 and sunflower-seed oil with an iodine value of 129 were used in the tests. When the results were plotted, the adulterated oils were found to lie to the left of the line within the sphere of pure oil. This result seemed to indicate that the method could not be used with certainty for the detection of the adulteration of linseed oil by semidrying oils of high iodine value.

Grape seed oil, R. W. DARNER (*North Dakota Sta. Spec. Bul.*, 2 (1913), No. 21, pp. 370-372).—After reviewing the literature in this regard (E. S. R., 29, p. 13), the results of an analysis of an oil obtained from the seeds of grapes grown in California are given. The golden yellow oil, when subjected to prolonged heating at 180° C. changes first to green and then to brown. The specific gravity at 15.5° was 0.9224, the refractive index at 20° was 1.475, iodine number 131.9, saponification number 192.6, unsaponifiable matter 0.88 per cent, acid number 1.11, acetyl value 81.09, Reichert-Meissl number 0.81, heat of bromination 22°, and Maumené test 82.5°. According to this the acetyl value of 144.5 reported by Horn needs confirmation.

Very small amounts of volatile acids, i. e., caproic, butyric, valeric, and caprylic, as evidenced by the Reichert-Meissl number, are present in grape seed oil. The Hehner number or insoluble acids was 93.9 per cent and the soluble

acids 0.35 per cent. The constants of the fatty acids were solidifying point 19.5, melting point 25°, iodine number 136.4, and saponification number 204.3.

"Summarizing the results obtained, the following is the approximate composition of the oil: Linolein 59.8, olein 29, palmitin 8.6, stearin 1, and unsaponifiable and undetermined matter 1.24 per cent."

From the drying tests it would seem that this oil with a dryer added will produce a very good paint.

Tomato-seed oil in Italy, L. J. KEENA (*Daily Cons. and Trade Rpts. [U. S.]*, 16 (1913), No. 273, p. 954).—In 1912 about 5,000 metric tons (2,204 lbs. each) of wet tomato residue was worked up and yielded 1,500 metric tons of dried residue. From this material 150 tons of tomato-seed oil, 800 tons of oil cake, and 500 tons of tomato peel were obtained. The oil is used extensively for the manufacture of soap, and experiments are under way for the manufacture of an edible oil from the crude oil. The cake is used as a stock feed and the peel as a fertilizer. At Parma the seeds from the tomato-preserving factories have been selling for 1.6 lira per quintal (14 cts. per 100 lbs.).

"In the vicinity of Naples, tomato residue in the wet state, just as it comes from the preserving factory, has been sold during the past year at 4.5 to 7.9 cts. per 100 lbs. The wet residue must be collected and dried daily as it ferments within 48 hours if allowed to stand. When dried it sells at Naples, f. o. b. cars, sack packing included, at \$1.75 to \$2.20 per 100 lbs. The industry is still considered to be in its infancy, but promises to become more important."

The effect of "lime-sulphur" spray manufacture on the eyesight, A. J. WEITH (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 12, p. 917).—"In making small batches of lime-sulphur spray in an uncovered kettle in the open air, symptoms very similar to the ones [previously noted (*E. S. R.*, 30, p. 16)] were experienced, although no permanent blurring of the vision resulted. The eyelids, however, became very red and were badly swollen. Since the trouble with the eyesight came only near the end of the 'cook,' and was very similar to the smarting sensation produced by getting the diluted spray in the eye, it was supposed that the disagreeable effects were caused by particles of solid material carried out with the escaping steam. No experiments were undertaken to prove this point."

Report of the activities of the Swiss Agricultural-Chemical Institute at Bern (Liebefeld) during the year 1912 (*Landw. Jahrb. Schweiz*, 27 (1913), No. 7, pp. 389-407).—During the year 9,164 samples were examined, which consisted of 4,073 fertilizers, 2,078 feeds, 2,969 samples of material obtained in vegetation experiments, 18 soils, and 26 miscellaneous materials. Some results of vegetation tests are also included.

METEOROLOGY—WATER.

The present condition of agricultural meteorology in Brazil, H. MOREZ (*Internat. Inst. Agr. [Rome]*, Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 9, pp. 1313-1316).—The status, object, and proposed work of the meteorological service organized under the ministry of agriculture in 1910 in cooperation with the various States of Brazil are briefly discussed.

[Meteorological observations], D. A. SEELEY (*Ann. Rpt. Sec. Bd. Agr. Mich.*, 52 (1913), pp. 111-126).—Tabulated daily and monthly summaries are given of observations during the year ended June 30, 1912, at East Lansing, Mich., on temperature, pressure, precipitation, cloudiness, wind movement, etc.

Meteorology (*Rpt. Lincoln Co. [Nev.] Expt. Farm, 1911-12*, pp. 31-36).—Tables are given which show the maximum and minimum temperatures and

the precipitation at the experiment farm from September 1, 1910, to December 31, 1912.

Meteorological summary for the year 1912, J. F. WILSON (*Wyoming Sta. Rpt. 1913, pp. 125-135, figs. 6*).—Monthly summaries are given of observations at Laramie, Wyo., during 1912 on temperature, pressure, precipitation, humidity, sunshine, cloudiness, and wind movement. A record of soil temperature at depths of 3, 6, 12, 24, 36, and 72 in. during 1912 is also given.

The highest temperature was 87° F., August 26; the lowest, -20°, February 4. The total precipitation was 14.79 in. The lowest relative humidity was 11 per cent, August 26. The greatest velocity of wind was 72 miles per hour, February 17.

On the amount of radioactive products in the atmosphere, S. SATÔ (*Sci. Rpts. Tôhoku Imp. Univ., ser. 1, 2 (1913), No. 4, pp. 171-174*).—In observations at Tôhoku University, Japan, by means of a negatively charged wire stretched horizontally above the ground, the numbers of atoms of radium and thorium emanations per cubic centimeter of air calculated from the results were, respectively, $N_E=1.5$, $N'_E=1 \times 10^{-4}$.

The soot-and-dust-fall of English towns and cities, J. B. C. KERSHAW (*Sci. Amer., 110 (1914), No. 3, pp. 63, 64, figs. 3*).—This is a brief account of the plan proposed by the International Conference on Smoke Abatement for the systematic study of the amount and character of the solid impurities in the atmosphere of large towns and manufacturing centers, and which has been put into effect in England and to a less extent in Germany. Reference is made to methods and apparatus used and to some of the results already obtained in such studies. These indicated that the soot and dust fall varies in certain English centers from 200 to 2,000 tons per square mile per annum.

The correlation of rainfall, J. PECK and E. C. SNOW (*Quart. Jour. Roy. Met. Soc. [London], 39 (1913), No. 168, pp. 307-316; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 12, p. 1844*).—From a study of the rainfall at 30 stations in southern and southeastern England during 1908 to 1911, inclusive, the authors conclude "that while the relative rainfall in December can be predicted from a knowledge of the rainfall in two or three of the previous months with a small degree of probability, that of June and July can not be foretold with the slightest degree of probability."

Rainfall as a determinant of soil moisture, F. SHREEVE (*Plant World, 17 (1914), No. 1, pp. 9-26, figs. 3*).—This paper presents "a digest of a short record of desert rainfall, interpreted in terms of its possible effect upon soil moisture; gives data showing the annual march of water content at three depths in a retentive clay soil; indicates the relative potency which different falls of rain were found to have in renewing the store of soil water; and estimates the relative efficiencies of various percentages of soil water for the maintenance of plant activity by correlating them with the concurrent rates of aerial evaporation." The observations were made at the Desert Laboratory near Tucson, Ariz.

Summarizing the results, it is stated that "the average annual rainfall at the Desert Laboratory is 14.60 in. There are two rainy seasons, that of the summer averages 63 days in length, but yields 54 per cent of the annual rainfall. The average number of rainy days is 61.5 per annum, on 46.2 of which the rainfall is less than 0.25 in. In six years there were 32 days with more than 0.75 in. of rain, and they yielded 46 per cent of the total rainfall of the six years. There have been periods of 140 days without rainfall of sufficient amount (0.15 in.) to affect the soil moisture.

"The march of soil moisture during the year is closely related to the amounts of the significant falls of rain, and the changes of moisture content are con-

servative at the lower depths (15 cm. and 30 cm.) in the heavy clay soil investigated. The moisture at 3 cm. falls as low as 1 per cent and that at 30 cm. rises to as much as 32 per cent. The average moisture of the soil from the surface to 30 cm. in the driest weeks of the year is 6.5 per cent, in the wettest is 29 per cent. At its minimum water content the clay soil contains about one-fourteenth of the annual supply of water furnished it by the normal rainfall.

"The weekly rate of atmospheric evaporation ranges from a minimum of 173 cc. to a maximum of 1,084 cc.—the annual total being 31,447 cc., in terms of loss from a porous cup atmometer. This is equivalent to a loss of 345 cc. per square centimeter from a free water surface. The ratio of evaporation to rainfall is as 9.3 is to 1.

"The ratio of evaporation to soil moisture fluctuates from a minimum amount to a maximum which are in the proportion of 1 to 10. The ratio of evaporation to soil moisture at the foot of the Santa Catalina Mountains is 9.7 times the same ratio for their summit. The annual amplitude of moisture conditions at the Desert Laboratory is as great, therefore, as that which exists in the most arid portion of the year between localities which are 5,000 vertical feet apart."

Effect of forests on run-off, J. C. STEVENS (*Jour. Electricity*, 32 (1914), Nos. 3, pp. 49-51, figs. 2; 4, pp. 73-75; 5, pp. 93-95; 6, pp. 116, 117, fig. 1; 7, pp. 135-137, figs. 3; 8, pp. 166, 167, fig. 1; 9, pp. 190, 191, figs. 4).—In a somewhat detailed discussion of the effects of forests on run-off, in which he deals with several watersheds as examples, the author reaches the conclusion "that uniformity of stream flow is influenced, practically in total, by factors entirely independent of forests, and if forests have any influence at all on this feature, it is very insignificant. The tendency they do possess, though almost infinitesimal, would be in a helpful direction in some cases, in others in a harmful direction."

Note on the chlorin content of rain water at Tortugas, Fla., R. B. DOLE (*Jour. Wash. Acad. Sci.*, 4 (1914), No. 1, pp. 3, 4; *abs. in Chem. Abs.*, 8 (1914), No. 4, p. 767).—A chlorin content of 2.9 parts per million of water was found.

Water, E. P. WIGHTMAN (*Pop. Sci. Mo.*, 84 (1914), No. 3, pp. 218-226).—The more important facts regarding the composition, properties, and importance in the economy of life of water in gaseous, liquid, and solid forms are summarized in this article.

Ground water and wells, H. HÖFER VON HEIMHALT (*Grundwasser und Quellen. Brunswick*, 1912, pp. XI+135, figs. 51).—The author has attempted in this work to present a hydrogeological text-book to serve as a guide in dealing with both the theoretical and practical sides of problems relating to ground water and wells. The principal topics discussed are the physics, chemistry, and biology of water supplies relative to quality and judgment; soil water from the infiltration of atmospheric precipitation; ground water, its origin, movement, and relation to streams and lakes; shape, grade, and variations of ground water level; ground water strata; influence of pumping on ground water; rock water; wells and their yield; dependence of quality of water on geological conditions; pollution of ground water and wells and means of protection; and water supplies for villages.

North Dakota waters, E. F. LADD (*North Dakota Sta. Rpt. 1912, pt. 3, pp. 449-483*).—This article notes the dangers from contamination of water supplies, discusses such subjects as solids and organic matter in water, boiler and antifoaming compounds, and purification of water, warns against the use of so-called household and faucet filters, and gives analyses of a large number of waters from wells and other sources in North Dakota.

The fertilizing value of sewage and sewage sludge, H. W. CLARK (*Mo. Bul. Bd. Health Mass., n. ser., 8 (1913), No. 12, pp. 473-490*).—Reviewing experience abroad as well as in this country, the author concludes that only under the most favorable conditions can the returns from sewage farms be made to pay operating expenses, and he maintains that an instance is yet to be cited where these returns pay both the cost of operation and interest on the capital invested. "The exceptions, perhaps, to this are certain tracts or farms in regions of low rainfall and where the sewage is valuable as a liquid, that is, for real irrigating purposes."

It is stated that the fairly strong domestic sewage of the city of Lawrence contains about 4.28 parts of nitrogen, 1 part of phosphoric acid, and 1.5 parts of potash per 100,000 parts of sewage, making the sewage worth as a fertilizer about 6 cts. per 1,000 gal.

It is stated that average American sewage contains about 2,400 lbs. of sedimentable matter in a million gallons, and this sludge contains fertilizing and fatty materials worth approximately \$15 to \$18. The recovery of the fatty matters and the preparation of the sludge for use as a fertilizer has been attempted in a few places, but the profitability of the practice is still in doubt.

"It has also been well proved that the nitrogen, phosphoric acid, etc., present are generally in a less assimilable form than the same bodies in ordinary commercial fertilizers. The sludge has value, however, and as the processes of drying, pressing, and fat separation are improved, and also as nitrogen advances in price, as seems inevitable, sewage sludge will become of greater agricultural value than it is at present, especially as the basis of a fertilizer enriched by the addition of potash, phosphates, etc."

SOILS—FERTILIZERS.

Field experiments and the interpretation of their results, A. GRÉGOIRE (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 1, pp. 13*).—The probable error in field experiments and methods of determining and reducing it are discussed. Reference is made to similar studies by Mercer and Hall, Wood and Stratton, Holtsmark, and Mitscherlich (*E. S. R., 27, p. 519*), and the results of experiments by Wagner are analyzed with reference to the probable error in them. As a result of such an analysis of 250 tests made at least in triplicate it was found that the probable error in each individual test exceeded 4.7 per cent in 50 cases out of 100, 6.6 per cent in 25 cases, 8.5 per cent in 9, and 10.5 per cent in 2.

The author's general conclusion is that out of 100 field experiments, as a whole, the probable error may exceed 5 per cent in 73 cases, 6 per cent in 64, 7 per cent in 52, 8 per cent in 39, 9 per cent in 30, 10 per cent in 18, 11 per cent in 9, and 12 per cent in 4. He shows that results from a single plat are almost always worthless. The probable error is decreased by increasing the number of plats, which should not be less than three.

With larger field experiments it is very difficult to keep the probable error below 10 per cent, and generally impossible to keep it below 5 per cent. This indicates that the larger majority of the results of field experiments, as ordinarily conducted, are not only not worthy of serious consideration but may be a veritable detriment to practical agriculture and discreditable to agronomic science.

Proposal for an international uniform classification of soils, D. A. LOUIS (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 8, Commun. D, pp. 5*).—

A simple scheme of classification and nomenclature proposed for international use in reporting results of field experiments is described and advocated.

The mechanical and chemical composition of the soils of the Sussex area, New Jersey, A. W. BLAIR and H. JENNING (*Geol. Survey N. J. Bul. 10 (1913), pp. 110, pls. 2*).—This bulletin, one of a series reporting work which has been conducted cooperatively by the Bureau of Soils of this Department, the Geological Survey, and the New Jersey State Station, briefly describes the geography and geology of the Sussex area in northern New Jersey, and discusses the mechanical and chemical composition of samples of 10 soil series and types encountered. Methods of analysis are described by R. B. Gage.

It is shown that the soils of the area are often deficient in lime, and magnesia is almost invariably present in excess of the lime. They are well supplied with potash and phosphoric acid, but frequently respond to applications of commercial fertilizers containing the latter in available form. There is more potash in the subsoil than in the soil, while the phosphoric acid is slightly less in the subsoil.

"Many of the soils are fairly well supplied with nitrogen, though some . . . are quite deficient in this material. Generally there is about three to four times as much nitrogen in the soil as in the subsoil. Applications of lime, together with more thorough cultivation and a more extended use of green manure crops, will do much toward making these soils more productive than they are at present."

Soil analyses, J. W. INCE (*North Dakota Sta. Rpt. 1912, pt. 3, pp. 439-445*).—Analyses of samples of alkali soils producing a poor crop showed "enough soluble salts . . . to prevent the growth of almost anything except possibly saltgrass." Treatments suggested for such soils are cultivation, application of manure and gypsum, and washing by irrigation and drainage. In pot experiments with oats, timothy, and alfalfa in these soils, gypsum, at the rate of 1,000 lbs. per acre, gave slightly better results than the untreated soil in the case of timothy and oats, and blood at the same rate acted very favorably.

Analyses of other soils for alkali and fertility constituents are reported.

Stations for soil investigations with reference to the soils of tropical South America, G. MEDINA (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 1, pp. 10*).—This article is based upon observations and experiments on the red soils of Brazil, which have undergone marked deterioration under culture in many cases. Comparative analyses of virgin forest soil and of similar soil after exhaustion by culture show a decline of nitrogen under culture from 0.76 to 0.07 per cent, of phosphoric acid from 0.53 to 0.09 per cent, of potash from 0.26 to 0.01 per cent, and of lime from 0.03 per cent to a trace, but an increase of iron oxid from 18.3 to 20.09 per cent and of silicates from 20.22 to 25.07 per cent. The soils are acid and poor in lime. The phosphoric acid is to a large extent, if not exclusively, combined with iron, and the potash is in the form of silicates. The soil conditions generally are unfavorable for active nitrification although there is rapid decomposition of the organic matter of the soil.

Fertilizer experiments on the red soils with coffee, sugar cane, rice, and rubber are briefly reported. These show, in general, that the soils respond generously to applications of fertilizers.

A classification of soils in general, with reference to altitude, latitude being a secondary consideration, is proposed and a plan of cooperative study of the red soils of Brazil and their relation to the fixation of potash, phosphates, and other fertilizing constituents is suggested.

The marsh formations on the German North Sea coast, H. GRUNER (*Die Marschbildungen an den Deutschen Nordseeküsten. Berlin, 1913, pp. 155, figs. 7*).—In this publication the kind and origin of the marsh lands of the region

are discussed in connection with the characteristics of the different soil formations and their mechanical, physical, and chemical structure. These marsh lands are said to have originated, principally, through glacial action, and gradual rising and sinking of the seacoast. Fourteen different soil formations are described, several of which apparently represent different stages of formation of the same soil caused by alternate rising and sinking of the coast. The majority of these formations are of high or average fertility, being for the most part characterized by a considerable content of lime and humus and an appreciable content of potash and phosphoric acid. The most important types appear to be the muck-sand and muck-clay soils, which contain much humus, lime carbonate, fine sand, and fine clay, and are said to be the deposits of receding floods. The more recent muck formations are saline. The less productive types are tough clays intermixed with coarse gravel and iron compounds.

The coast marsh districts and the so-called river and lake marshes of the region are described with reference to the distribution of the soil types, and discussed from the standpoint of improvement and profitable utilization.

The soils of Uruguay, J. PUIG Y NATTINO (*Min. Indus. [Uruguay], Insp. Nac. Ganaderia y Agr. Bol.* 6 (1913), pp. 30+4, pl. 1).—This bulletin gives results of physical and chemical analyses of 138 soil samples from different States in Uruguay, a chart showing the location of the soils by States, and a classification of the soils as regards their physical and chemical properties and plant food content.

The parent rocks and consequently the soil formations are very varied, the soils usually being formed by weathered materials transported from more or less distant points. The predominating soil types show in general sufficiently firm and resistant qualities due to the relatively high content of fine sand and clay. The soils are generally relatively deficient in lime, although some show a high lime content, and are on the whole rich in humus and nitrogen. The phosphoric acid content appears to be usually a little low, the potash content on the whole relatively high.

The determination of the reaction and the basicity of soils and their importance in soil examination, H. R. CHRISTENSEN (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 3, pp. 10*).—This article discusses the importance and methods of determining the reaction and basicity of soils. It points out their relation not only to the growth of higher plants but also to the activity of the microflora of the soil. These determinations furnish a valuable indication of the lime and other fertilizer needs of the soil, the crops best adapted to it, the weeds and other injurious plants, and plant diseases most likely to thrive in it.

Experiments with water solutions of the soil, G. LEONCINI and G. MASONI (*Staz. Sper. Agr. Ital.*, 46 (1913), No. 7-8, pp. 525-539).—Studies of soil solutions showed their power of flocculation to be inversely proportional to the quantity of kaolin remaining in suspension in a solution after a fixed time, comparison being made with the amount held in suspension in distilled water under the same conditions. The powers of flocculation of soil solutions varied with the soil and with the method of preparing the solutions.

It is concluded that the power of flocculation of a soil solution is not only an index of the individual properties of a soil, but also indicates accurate methods of analysis.

Circulation of nitrates in the soil, L. MALPEAUX and G. LEFORT (*Ann. Sci. Agron.*, 4. ser., 2 (1913), II, No. 6, pp. 705-726, figs. 2; *abs. in Chem. Abs.*, 8 (1914), No. 7, p. 1320).—In a continuation of previous experiments (*E. S. R.*, 28, p. 720), the authors observed the influence of sodium nitrate fertilization at the surface and at depths of 5, 10, 17, and 30 cm. and of rainfall and capillarity

on the diffusion of the nitrate in fallowed and cropped soils, and also the effect of depth of fertilization on the growth and yield of sugar beets.

The best average results were observed with the deeper fertilization, the nitrate diffusion in both fallowed and cropped soils being more prompt and uniform, and the nitrate absorption by sugar beets in the cropped soil and the growth and yield of sugar beets being greater. Although the total yield of sugar per acre was greater with deeper fertilization, the percentage of sugar in the beets was slightly greater with shallow fertilization. It is concluded that for prompt and uniform diffusion of nitrates in cultivated soil, fertilization should take place with the cultivation preceding the seeding. The accumulation and consequent utilization of nitrates near the surface by plants is attributed to capillarity. The general conclusion is that nitrates are not carried out of reach of plant roots by summer rains and that it is therefore useless to add the fertilizer at intervals in fractional amounts.

Nitrate formation in forest soil, K. VOGEL VON FALCKENSTEIN (*Internat. Mitt. Bodenk.*, 3 (1913), No. 6, pp. 494-528).—Investigations with various kinds of soils showed that light forest soils poor in lime, usually with a matted litter covering overlying humus mineral soils, produced under favorable moisture conditions sufficient quantities of nitrate to satisfy the demands of the forest growth. In such soils, when dry, a new well-decomposed litter covering of pine needles and beech leaves strongly promoted nitrate formation. Black humus apparently had only an indirect effect and did not promote nitrification, and a dry peat covering was found to aid but little in nitrate formation. Mixing the litter covering with the sand soils increased nitrate formation. It is stated that dry peat layers when treated in this way should be limed to hasten decomposition.

In wet sandstone soils deficient in lime imperfect decomposition of the usually large accumulation of humus caused a poor utilization of the total nitrogen, which was most marked with peat litter coverings.

Heavy forest soils rich in lime were always found to be richer in nitrates than light soils poor in lime. The matted litter covering is said to be usually absent in such soils on account of rapid decomposition, but the humus-rich mineral layers produce considerable quantities of nitrate. The humus in these layers is protected from too rapid decomposition but becomes very active when air is admitted, and leaching away of nitrates is in large measure prevented by the physical condition of the soil. The author concludes that the condition of a soil as to nitrate formation serves as an indication of its forest-producing powers.

Rothamsted investigations on the production of plant food in the soil, E. J. RUSSELL (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 3, pp. 6*).—A brief account is given of investigations at Rothamsted, more particularly on the nitrogen supply of soils.

A list is given of publications on the subject by the author and his associates. Methods for the biochemical study of soil, J. STOKLASA (*X. Cong. Internat. Agr. Gand, 1913, Sect. 2, Question 3, pp. 14*).—A scheme for the complete biochemical examination of soils is outlined.

[Soil bacteriological investigations], F. H. H. VAN SUCHTELEN (*Michigan Sta. Rpt. 1913, pp. 149-155*).—The opinion is expressed that soil bacteriology can be successfully developed only by a thorough study of the soil solution in relation to the growth of bacteria. A method of obtaining unaltered soil solution by means of displacement with paraffin oil is briefly referred to, and results of chemical and physiological studies with solutions so obtained are noted.

Investigations on soil fatigue, H. KASERER (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien, 2 (1913), No. 2, pp. 375-410, figs. 6; abs. in Chem.*

Ztg., 37 (1913), No. 116, p. 1175).—Numerous investigations of flax and pea sickness of soil showed that the repeated growing of flax or peas caused the so-called germination fatigue, by which the seeds rotted before or during germination. The ability of the seeds to resist this action was found to depend more or less on the conditions of seed bed and soil, and on moisture and temperature conditions, etc. Soils which were germination-tired for peas had more or less the same effect on flax and vice versa. According to the author, germination fatigue is different from growth fatigue, which was particularly observed with flax. Well-cultivated plants grew poorly in healthy soil to which about 15 per cent of flax-sick soil had been added. Similarly, a small addition of good flax straw to the soil had a bad effect on the growth of flax.

While the germination fatigue disappears over winter, growth fatigue is said to exist a longer time. It is stated that only by further investigation can it be determined whether the germination and growth fatigue are due to the activity of micro-organisms or to poisonous substances excreted by plants and which may also be contained in straw.

Essentials in the management of California soils, C. B. LIPMAN (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 1, pp. 19-26).—The author points out that the deep soils of the arid region are due to the slow formation of clay resulting from the relatively infrequent action of the leaching and weathering agencies. He advocates as the six most important measures in maintaining the fertility of California soils (1) deep plowing, (2) prevention of formation or breaking up of plowsole, (3) irrigation in deep furrows, (4) deep incorporation of manure and fertilizers, (5) frequent summer cultivation, and (6) green manuring and the maintenance of the humus and nitrogen supply.

The effect of treating sand soil with moor soil, C. KRÜGER (*Mitt. Ver. Förd. Moorkultur Deut. Reiche*, 30 (1912), p. 402; *abs. in Zentbl. Agr. Chem.*, 42 (1913), No. 10, pp. 651, 652).—Treatment of sand soil with different amounts of moor soils and treatment of quartz sand subsoil with different amounts of moor humus slightly increased the total yield of oats but decreased the percentage of grain in the total yield, and also the single grain weight. The treated soils had always a higher water content than the untreated soils, but relatively little of it was available to plants. It is thought that such treatment in dry seasons without irrigation would result in a considerably decreased yield.

Gullying and its prevention, F. H. H. CALHOUN (*South Carolina Sta. Circ.* 20 (1913), pp. 36, pl. 1, figs. 13).—This circular contains a popular discussion of the cause of erosion of farm lands, particularly through the agency of water, the necessity for its prevention, the means of checking the erosion, and the methods of restoring eroded land to its original fertility.

The disadvantageous results of unchecked washing of fields are pointed out as (1) sheet erosion, which tends to strip the tops of the hills of fertile soil and in time covers the lower slopes with less productive debris; (2) the formation of gullies, which render cultivation difficult, allow the escape of soil moisture, humus, natural plant food, and commercial fertilizers; (3) the change of soil texture from desirable loams to clays and sands; (4) the covering of fertile bottom lands with material from gullies; (5) the filling of rivers, harbors, and reservoirs with sediment; and (6) the depreciation of farm-land values.

Means suggested and described for checking and remedying these harmful results are (1) proper cultivation, (2) deep plowing, (3) preventing incipient gullying, (4) hillside ditching, (5) proper terracing, (6) filling gullies by leveling or by obstructions, and (7) reforestation.

Green manuring in California, C. B. LIPMAN (*California Sta. Circ.* 110 (1913), pp. 3).—A brief popular summary of information on this subject.

Efficiency of soluble manures in dry years, F. LÉONARDON (*Rev. Agr. et Vit. Afrique Nord*, 1913, Nos. 49, pp. 151-155; 50, pp. 180-186; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, pp. 553-557; *Chem. Abs.*, 8 (1914), No. 5, p. 979).—The results of demonstration experiments with various crops in different parts of Algeria and Tunis in 1911-12 are summarized, showing in general the high efficiency of mineral fertilizers as compared with organic manures. Sodium nitrate was especially effective. The results indicated that there is a minimum of moisture below which fertilizers give little or no benefit. There was little increase from the use of fertilizers on soils containing less than 15 per cent of moisture.

Soil nitrogen.—Green manures (*Georgia Sta. Circ.* 71 (1914), pp. 2).—In this circular some practical deductions are drawn from the investigations previously noted (*E. S. R.*, 30, p. 517), viz, that cotton-seed meal, tankage, and dried blood are nitrified in the acid soils experimented with more readily than ammonium sulphate, unless the soils are limed, but since the field experiments of the station have shown that the sulphate is a more effective fertilizer for corn and cotton than the other substances named it apparently can be readily utilized by crops whether nitrified or not.

The further inference is drawn from the results that the soil bacteria do not ferment green manures in such a way as to produce acids, "but on the other hand their action is such as to neutralize partly any acid that might be present in the soil."

Nine years' experiments with the new nitrogenous fertilizers, S. RHODIN (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 75 (1913), pp. 17; *K. Landtbr. Akad. Handl. och Tidskr.*, 52 (1913), No. 3, pp. 192-206).—A summary is given of experiments with sodium nitrate, ammonium sulphate, calcium nitrate, and calcium cyanamid for cereals, hay, root crops, and potatoes conducted by the Swedish experiment station during the period 1903 to 1911. Of the fertilizers mentioned the calcium nitrate produced the best results for grass, roots, and potatoes, while for cereals, especially oats, which do not require much lime, it proved inferior to sodium nitrate. Even in this case, however, the application of calcium nitrate gave profitable returns.

The after effects of the fertilizers were studied in a number of trials with sodium nitrate, ammonium sulphate, and cyanamid on a stiff clay. On the average for three crops of spring grains and two of potatoes the relative increase in yield of dry matter during the second and third years from the nitrogenous fertilizers, above that of the control plats, was as follows: Sodium nitrate 100, ammonium sulphate 115, and calcium cyanamid 108.

The nitrate position and results (*Economist*, 78 (1914), No. 3672, pp. 71, 72).—The total exports of nitrate from Chile are stated to have been slightly greater in 1913 than in 1912. Europe and Egypt took 1,816,170 tons, about 6 per cent less, and the United States 560,010 tons, about 25 per cent more. An attempt was made to restrict production but was not entirely successful. It is thought that the prospect for greatly increased use is not good unless there is still further decline in price.

Phosphate deposits in southwestern Virginia, G. W. STOSE (*U. S. Geol. Survey Buls.* 540-L (1913), pp. 16, figs. 3; 540 (1914), pp. 383-398, figs. 3; *abs. in Amer. Fert.*, 40 (1914), No. 2, pp. 54-56, 60, fig. 1).—Deposits observed at two places, one near Saltville and the other near Marion, are described. The phosphate bed is composed of grains and small pebbles of quartz, glauconite, and phosphate nodules. The richest sample of phosphate rock collected contains 27.17 per cent of phosphoric acid. The commercial importance of the deposits was not determined.

The use of lime and gypsum on California soils, C. B. LIPMAN (*California Sta. Circ.* 111 (1913), pp. 4).—A brief popular summary of information on this subject.

New fertilizers, D. ZOLLA (*Rev. Gén Sci.*, 24 (1913), No. 19, pp. 730-732).—The results of experiments by various investigators with salts of lead, uranium, and manganese, calcium nitrate, and cyanamid are briefly reviewed.

The influence of catalytic substances, G. RIVIÈRE and G. BAILHACHE (*Jour. Soc. Nat. Hort. France*, 4. ser., 14 (1913), Dec., pp. 782-788).—Series of plat experiments extending over several years to test the influence of sodium arsenate, manganese chlorid, and ammonium vanadate on winter wheat; sodium borate, fluorid, and iodid on spring wheat; zinc sulphate, sodium arsenate, manganese sulphate, and ammonium vanadate on oats; and lithium carbonate, rubidium chlorid, rubidium alum, and cesium chlorid on beets are reported.

As a rule the application of the substances named in amounts generally not exceeding in any case 89 lbs. per acre increased the yield to a marked extent. There were, however, in numerous unexplained cases, unfavorable results indicating the need for further careful study of the subject before the use of catalytic fertilizers in practice can be safely recommended.

Sulphur and iron pyrites as fertilizers, V. VERMOREL and E. DANTHONY (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 47, pp. 651-653; *Bul. Soc. Nat. Agr. France*, 73 (1913), No. 9, pp. 696-702; *Engrais*, 28 (1913), No. 47, pp. 1304-1306; *Bul. Agr. Algérie et Tunisie*, 19 (1913), No. 20, pp. 397-400; *abs. in Jour. Bd. Agr. [London]*, 20 (1914), No. 10, pp. 901, 902; *Chem. Abs.*, 8 (1914), No. 3, pp. 545, 546; *Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 1, pp. 61-63).—In the pot experiments reported it was found that sulphur applied at rates of from 44.6 to 89.2 lbs. per acre and iron pyrites (containing 50 per cent sulphur) at rates of 89.2 to 178.5 lbs. per acre increased the yields of wheat and beans 30 to 60 per cent when used in combination with organic matter (with dried blood as the source of nitrogen). They were without effect when used on soils lacking in organic matter and receiving nitrogen in the form of sodium nitrate. Better results were obtained when the sulphur and pyrites were mixed with the soil than when applied as a top dressing. Pyrites were more effective than sulphur on wheat and less effective on beans.

The law of minimum (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 43, pp. 595-598, figs. 4).—The first part of this article discusses the law of minimum as defined by Mitscherlich. The second part illustrates by diagram the application of the law.

The use of commercial fertilizers in Canada, L. E. EMSLIE (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, pp. 558-560).—It is stated that "the use of commercial fertilizers in Canada has scarcely passed the initial stage, although in the Maritime Provinces, more especially in the fruit and potato-growing districts, fertilizers have been popular for years. Ontario and Quebec have, during the past five years, been giving the subject more attention and may be expected rapidly to increase their consumption from this stage. British Columbia quickly learned the value of fertilizers and takes high rank as a consumer. This year a Victoria firm shipped a carload of fertilizer to Dawson City in the Yukon. The Provinces of the middle-west will not be heavy consumers for many years to come, although the use of fertilizers there has commenced, chiefly among market gardeners and potato growers, but they are also being used to a small extent by grain growers. . . . In the younger Provinces of Alberta and Saskatchewan the interest in the fertilizer question seems greater than in Manitoba."

Fertilizers to the value of \$1,773,861 were imported into Canada during the year ended February 29, 1912.

Data regarding the relative care and use of farm manures in the different Provinces are given.

The fertilizer industry (*Thirteenth Census U. S., 10 (1910), pp. 575-585, figs. 2*).—Statistics of the fertilizer industry in the United States for 1909 are summarized and discussed, and the growth of the industry since 1859 is indicated. In 1909 there were 550 fertilizer establishments, employing 21,950 persons, representing a capital of \$121,537,451, and yielding products valued at \$103,960,213.

AGRICULTURAL BOTANY.

Indicator significance of vegetation in Tooele Valley, Utah, T. H. KEARNEY ET AL. (*U. S. Dept. Agr., Jour. Agr. Research, 1 (1914), No. 5, pp. 365-417, pls. 7, figs. 13*).—A study is reported of the vegetation of the Tooele Valley in central Utah in which an attempt was made to correlate the distribution of the vegetation with the physical and chemical properties of the soil with a view to ascertaining the agricultural value of the soil.

It was found that in this valley the different types of native vegetation indicated the conditions of soil moisture and salinity of the land on which they were found and afforded a basis for estimating its capabilities for crop production. The sagebrush (*Artemisia tridentata*) association indicates land well adapted to both dry land and irrigation farming. The Kochia (*K. vestita*) association areas are adapted to irrigation farming, although the impervious nature of the soil might hinder washing out the salts to a depth which would permit profitable crop production. The shadscale (*Atriplex confertifolia*) association occupies land in which dry farming is rather precarious, but where water is available for irrigation the salts could probably be leached to a greater depth than on Kochia land. The greasewood-shadscale (*Sarcobatus vermiculatus* and *A. confertifolia*) association occupies land that is strongly saline below the depth of the first foot and is not suitable for dry farming, but can be made to produce good crops under irrigation if drainage is provided. The presence of the grass flat vegetation indicates a soil of high moisture capacity, somewhat saline, and not suitable for crop production unless drained. The salt flats are not adapted to crop production under present conditions.

Stomatal characteristics of varieties of sugar cane, W. R. DUNLOP (*West Indian Bul., 13 (1913), No. 4, pp. 314-323, pls. 2*).—A study has been made of varieties of sugar cane to determine whether there is any relation between the stomata of the leaves and the resistance of plants to drought. A considerable number of varieties were microscopically examined, and it was found that stomatal density per unit of area is so characteristic of certain varieties that this factor may be used in their recognition. There seems to be some evidence that susceptibility to drought is affected by extremes as regards the ratio of the total stomatal area to the entire area of the foliage. The curling of the leaves is considered more important in limiting the effective action of the stomata than the stomata themselves. It is thought that the distribution of certain varieties of cane would be limited to definite regions were it not for the correlation between leaf habit and stomatal characteristics.

Stomata and drought resistance in maize, H. A. WAGER (*So. African Jour. Sci., 9 (1913), No. 8, pp. 183-185*).—The author reports on a study of the relationship between number of stomata present and power of drought resistance in leaves of Indian corn. It is stated that the stomata were larger but less

numerous on the upper side of the leaves. The author inclines to the view that the drought resisting capacity does not bear any close relation to number of stomata, but that it is related to the presence of a peculiar structure on the epidermis of the leaves in the form of small special groups of absorbing and storing cells, which are to be further investigated.

Studies in the chlorophyll group.—XIX, The inconstancy of chlorophyll quotients in leaves and their biological meaning, H. BOROWSKA and L. MARCHLEWSKI (*Biochem. Ztschr.*, 57 (1913), No. 5-6, pp. 423-429).—This is a partial review of work previously reported by Jacobson and Marchlewski (E. S. R., 28, pp. 110, 608), with notes replying to some criticisms offered thereto.

The rôle of oxygen in germination, C. A. SHULL (*Bot. Gaz.*, 57 (1914), No. 1, pp. 64-69).—In a previous study (E. S. R., 26, p. 531), the author found that there was either a change in permeability of the seed coat of *Xanthium* or a change in oxygen need of the embryo during the winter. It was believed that a careful measurement of the oxygen used by the seed would show which of these changes occurred, and a preliminary report is given of results obtained in studying the rôle of oxygen in the germination of this seed.

In the experiments the two lower seeds were placed in one chamber of the respirometer and the seed coats in the other chamber. In 22.5 hours the seeds used 0.475 cc. of oxygen, while the seed coats used 0.098 cc., indicating that possibly the seed coats were partly responsible for the respiration of the intact seeds. Later the respiration of the lower and upper seeds under atmospheric conditions was compared, and finally in atmospheres of oxygen. It was found that the two lower seeds in the atmosphere used 0.687 cc. of oxygen in 42.3 hours, while the same number of lower seeds used 1.007 cc. in 12.5 hours in 95 per cent oxygen. The upper seeds used 0.509 cc. in 43.2 hours in the atmosphere, and 0.4406 in 12.5 hours in 96 per cent oxygen.

This seems to indicate that an increase in the oxygen supply brings about an immediate and rapid increase in the rate of oxygen absorption and an immediate germination of the seeds. The author states that, owing to the complexity of the oxygen rôle in physiological processes, it is difficult to say which function or functions are affected. It seems certain, however, that the oxygen acts as a limiting factor on some function. The exact method by which the absence of oxygen delays germination, it is said, can be determined only by further investigation.

Studies on the assimilation of atmospheric nitrogen by yeast and fungi, P. LINDNER and C. W. NAUMANN (*Wehnschr. Brau.*, 30 (1913), No. 47, pp. 589-592).—Reviewing briefly recent contributions in this connection and discussing repeated tests made with *Endoblastoderma salmonicolor*, *Saccharomyces farinosus*, and *Oidium lactis*, the authors conclude that in the experiments cited atmospheric nitrogen was not assimilated by these forms.

The relation between the transpiration stream and the absorption of salts, H. HASSELBRING (*Bot. Gaz.*, 57 (1914), No. 1, pp. 72, 73; *abs. in Science*, n. ser., 39 (1914), No. 998, p. 259).—An account is given of some experiments conducted by the author during the winter of 1908-9 while connected with the experiment station in Cuba. These were carried on with tobacco plants under cheese-cloth shade and in the open to determine the comparative transpiration of tobacco plants.

The plants grown in the open absorbed about 28 per cent more water than those grown under shade. The plants which absorbed and transpired the greater quantity of water contained the smaller percentage and the smaller absolute quantity of ash. It appears from these experiments that the absorption of salts by roots is independent of the absorption of water and that the

transpiration stream does not exert an accelerating effect on the entrance of salts.

Influence of the salts common in alkali soils upon the growth of rice plant, I-IV, K. MIYAKE (*Bot. Mag. [Tokyo]*, 27 (1913), Nos. 321, pp. 173-182; 322, pp. 193-204; 323, pp. 224-233; 324, pp. 268-270).—The author carried out a number of tests regarding the influence upon the growth of young rice seedlings exerted by chlorids, nitrates, sulphates, and carbonates of sodium, calcium, magnesium, and potassium usually found in alkali soils, the conclusions from which may be summarized as follows:

The alkali and related salts, tested singly, proved to be toxic or stimulating according to concentration, each having its maximal points; but tested in combination with each other, their toxic effects may decrease or even disappear, in some cases given the antagonistic action of salts (otherwise toxic to the plant) for each other being ascribed to the influences of the ions present owing to the dissociation of the salts. The curve of antagonism between sodium and potassium salts shows two maxima.

Mutation in *Penicillium glaucum* and *Aspergillus niger* under the action of known factors, H. J. WATERMAN (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1912), pt. 1, pp. 124-128).—Studies carried out with cultures of *P. glaucum* showed that this fungus exhibits mutations when cultivated in the presence of any one of several acids tested, as evidenced by differences in odor, tenacity, number of spores, etc. Experiments with *A. niger* showed enormous differences in metabolism of three strains obtained. It is claimed that by the methods employed it is possible to show the existence of mutations even when visible external differences between the cultures are lacking.

Action of hydrogen ions, boric acid, copper, manganese, zinc, and rubidium on the metabolism of *Aspergillus niger*, H. J. WATERMAN (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1912), pt. 1, pp. 753-764).—Reporting the results of studies on metabolism, the author states that mutation was again apparent in the behavior of *A. niger* in cultures containing one or more of these components. Metabolism was but little or not at all influenced by addition of sulphuric acid or zinc and copper salts (the latter counteracting spore formation). Manganese acted favorably on the rapidity of spore formation. Rubidium, substituted for potassium, reduced spore formation but increased mold weight. This action is not considered as necessarily favorable, as in certain concentrations of copper sulphate, zinc chlorid, and zinc sulphate, a resulting increase of weight is inversely proportional to spore formation.

Relations of lipoids to differences in the electrical potential in plant organs, J. LOEB and R. BEUTNER (*Biochem. Ztschr.*, 51 (1913), No. 4, pp. 288-299).—The authors summarize the conclusions reached as the result of this study, in the claim that differences of potential noted in certain living plant organs are determined by the presence of a superficial layer of phosphatids or of allied substances not readily soluble in water. Variations in the characters of these, as regards their solvents, are related to the electrical differences noted.

Influence of anesthetics on superficial differences of electrical potential in plant and animal tissues, J. LOEB and R. BEUTNER (*Biochem. Ztschr.*, 51 (1913), No. 4, pp. 300-306).—Claiming to have shown, in previous communications cited, that the differences of potential observable between unwounded surfaces of plant organs and aqueous solutions of salts, present sharply defined and reversible alterations with differences in concentration of the latter, also that nonelectrolytes, as sugar and urea, show no such behavior, the authors report results of further study regarding the influence of several anesthetics, etc., in connection with constant concentration as regards the salt content, employing therein leaves of rubber plant or apple and muscles of the frog.

Along with more specific conclusions it is stated that considerable additions of alcohol or ether produce a reversible lowering of the potential difference between the living organ and the aqueous solution. This, it is thought, may be related to a change from a soluble to an insoluble phase in case of ether. The differences were more marked in case of vegetable tissue than in the experiments with animal tissue.

Comparative histology of alfalfa and clovers, KATE B. WINTON (*Bot. Gaz.*, 57 (1914), No. 1, pp. 53-63, figs. 8).—On account of the common use of alfalfa and clovers for preparing alfalfa meal, the author has made a study of the different species and has presented a scheme for the identification of alfalfa, red clover, and alsike clover, based on the characters of the epidermal cells and the unicellular hairs of the leaf.

On the mode of inheritance of certain characters in double-throwing stocks, EDITH R. SAUNDERS (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 10 (1913), No. 4, pp. 297-310).—The author replies to a criticism of reports of some of her work on the inheritance of doubleness in flowers (*E. S. R.*, 26, p. 433; 30, p. 330), claiming that sex-limited inheritance can not explain the phenomena of inheritance of doubleness and of plastid color in stocks.

Mutation in tobacco, H. K. HAYES and E. G. BEINHART (*Science*, n. ser., 39 (1914), No. 992, pp. 34, 35).—The authors give a description of a variation that appeared in 1912 in a field of Connecticut shade-grown tobacco. The variety of tobacco known as the Cuban had been grown since 1904 in the Connecticut Valley, and in 1912 over 100 acres of tobacco was grown from the seed of the 1910 crop at the Windsor Tobacco Growers' Corporation. When the crop was harvested a plant was noticed that was much taller than the others and bore a large number of unpicked leaves. This plant, together with two others that were later discovered, were transferred to the greenhouse of the Connecticut State Station and there produced considerable seed. In 1913 about 5,000 plants were grown from this seed and these were all true to the new type.

In 1913 a planting was again made of 200 acres of plants from the original 1910 seed, and although a thorough search was made no mutating plants were discovered. Two mutants were found at other plantations, however, that presented the same character as that described above. Other mutations have been found, indicating that the same mutation must have taken place several times.

Breeding medicinal plants, F. A. MILLER (*Amer. Jour. Pharm.*, 85 (1913), No. 7, pp. 291-301, figs. 5; *Lilly Sci. Bul.*, 1. ser., No. 4 (1914), pp. 127-135, figs. 4).—An account is given of experiments made to secure more uniform strains with higher alkaloid content of belladonna (*Atropa belladonna*), henbane (*Hyoscyamus niger*), stramonium (*Datura stramonium* and *D. tatula*), and digitalis (*Digitalis purpurea*). In connection with the last comparisons were made of 32 species and varieties to determine their yield, cultural characters, flowering period, and the effect of hybridizing on these various characters.

On the apparent absence of apogamy in *Oenothera*, R. R. GATES (*Science*, n. ser., 39 (1914), No. 992, pp. 37, 38).—In 1909 the author described some experiments which suggested that *Oenothera* was occasionally apogamous. In 1912 experiments were again carried on, much more extensively than previously, the results of which were wholly negative, showing that if apogamy occurs in *O. lutea*, it must be very rare. The author also calls attention to a recently observed case of parthenocarpy in a race of *O. muricata*, in which capsules developed normally but contained undeveloped ovules instead of seeds.

Lectures on agricultural bacteriology, F. LÖHNIS (*Vorlesungen über landwirtschaftliche Bakteriologie*. Berlin, 1913, pp. VIII+398, pls. 10, figs.

60).—The general portion of these lectures deals with the morphology, development, cultivation, and powers of micro-organisms and means of combating injurious forms. The specialized portion deals with bacteriology pertaining to feeds, dairy products, soils, and fertilizers.

FIELD CROPS.

On the application of the method of least squares in agriculture, O. FRÖHLICH (*Mitt. Landw. Inst. Breslau*, 6 (1913), No. 5, pp. 683-703, fig. 1).—In this article the author discusses the arithmetical mean, observation errors, the measure of exactness, the law of large numbers, graphical comparisons, and the solution of normal comparisons, and illustrates these from actual practice.

On the application of the method of least squares, J. FRISCHAUF (*Landw. Jahrb.*, 43 (1912), No. 3, pp. 501-508).—This discusses the relation between the number of observations and the number of constants to be determined, and presents formulas for use in estimating the experimental errors, which are classed as "accidental" and "systematic" errors.

On the standing room of individual plants in plant breeding, E. A. MITSCHERLICH (*Ztschr. Pflanzenzücht.*, 1 (1913), No. 3, pp. 275-285, figs. 2).—The distance between individual plants to be used as breeders should be such as to avoid the influence of both the climatic vegetative factors and the neighboring plants. It is noted that the soil should be highly fertilized so as to reduce the possible inequalities in soil fertility. To get satisfactory results from the multiplication plats it is advised that they be 4 by 12.5 meters, arranged in series of 7 each, and repeated 4 times, so that number 1 shall be compared with number 7, 2 with 8, and 3 with 9, etc.

[Demonstration work] (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 6, pp. 279-296, pls. 5).—These articles comprise notes on crop selection, drainage, preparation of seed beds, methods of planting, soil improvement, and crop rotation, and include discussions of demonstration work in the Provinces around Manila by W. A. Mace; in Iloilo-Capiz by S. H. Sherard; in the island of Cebu by G. G. Weathersbee; in the Province of Batangas by H. T. Nielsen; and in the Mountain Province and Nueva Vizcaya by A. M. Burton.

[Reports on field crops] (*Union So. Africa Dept. Agr. Rpt. 1910-11*, pp. 21, 22, 29, 30, 229-253, 267-304, 453-466, 475-483, 515-518, 523-526, 541-544, 568-592, 603-615, 636-638, 641, 642, pl. 1).—These papers give summaries of continued work with tobacco, cotton, dry-land farming, maize, strawberry clover (*Trifolium fragiferum*) and other clovers, Tangier pea (*Lathyrus tingitanus*), Florida beggar weed (*Desmodium tortuosum*), serradella, Kanker-bosje (*Sutherlandia frutescens*), saltbushes (*Atriplex leptocarpa canescens*), blue grama (*Bouteloua gracilis*), Australian blue grass (*Andropogon sericeus*), sisal hemp, goats rue (*Galega officinalis*), sulla (*Hedysarum coronarium*), teff grass, alfalfa, thousand-headed kale, Mitchell grass (*Astrebala pectinata*), soy beans, Natal sugar beans, Rhodes grass, guinea grass, Kikuyu grass, spineless cactus (*Opuntia coccinellifera*), New Zealand flax, Algerian spinach (*Chenopodium amaranticola*), chayote (*Sechium edule*), Helianti, indigo (*Indigofera arrecta*), tree lucern (*Medicago arborea*), weeds, velvet beans, cowpeas, peanuts, grain inspection, root crops, potatoes, sugar cane, Kafir corn, wheat, native grasses, and oats.

New sources of nitrogen (*County Northumb. Ed. Com. Bul. 19 (1913)*, pp. 91, 92).—Slightly inferior yields of oats were obtained with calcium cyanamid than with sulphate of ammonia. With oats, hay, and mangels, nitrate of lime compared favorably with nitrate of soda.

Germination experiments with cereals in light and in darkness, A. BURGERSTEIN (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 8, pp. 849-861).—From experiments carried out in 1912 and 1913 the author concludes that cereal seeds germinate somewhat more slowly in diffused light than in darkness, but that light or darkness has little influence on the germinative ability. The temperature was maintained at between 18 and 20° C. It is noted that large oat seeds show a greater germinative energy than small ones.

Observations on cereals in trial plats, W. G. SMITH and T. ANDERSON (*Edinb. and East of Scot. Col. Agr. Rpt.* 30 (1913), pp. 26, pls. 3).—It is noted that when these plats were covered with a small mesh wire netting the ripening of the cereals was retarded more than 3 weeks in some cases, especially during cool wet seasons. It was found that, as a rule, grains of barley with a smooth rachilla produced plants with stronger straw and better grain than those from the same sample with a hairy rachilla. Two years' selection with barley did not seem to have any influence in reducing the number of spikes. In crossing barley it was observed that serrated dorsal veins of the kernels and the hairy rachilla appeared as dominant characters in the F_1 generation.

The influence of local conditions on the development of cereals with special reference to Göttingen variation, VON SEELHORST (*Jahrb. Deut. Landw. Gesell.*, 27 (1912), No. 2, pp. 374-386, pls. 4, fig. 1).—Similar work by Polle has already been noted (*E. S. R.*, 30, p. 136.)

The influence of different spacing on the growth of the plant, K. GRUNDMANN (*Deut. Landw. Presse*, 40 (1913), Nos. 71, pp. 846-848; 72, pp. 856, 857).—This article reports results of an investigation covering observations on the development of the plant, yield of grain, and character of the grain of wheat and rye as influenced by the spacing of breeding plants, so that each received from 36 to 200 sq. cm. From the results of 2 years' work the author concludes that a spacing of 5 by 20 cm. is the most favorable for selected plants which are to be used in breeding, and that a spacing of 3 by 20 cm. is the best suited for the multiplication plats.

Experiments bearing on feeding off cereal crops with sheep, A. J. PERKINS and W. J. SPAFFORD (*Jour. Dept. Agr. So. Aust.*, 16 (1913), Nos. 9, pp. 935-964, figs. 11; 11, pp. 1225-1238, figs. 5).—This gives results in tabular form of 3 years' experiments carried on to determine the effect produced upon yields by removing by pasturing or cutting the early growth of wheat, barley, and oats. The data show (1) that hay yields suffered by even judicious pasturing. (2) that in order to avoid lodging, pasturing was found advisable when there was an "overrank" winter growth, and that it should be done as rapidly as possible by crowding with sheep, (3) that pasturing should not be done in wet weather, late in the season, in frosty weather, and (4) that the percentage of smut in the grain was reduced by pasturing.

On the mechanics of the unfolding of the embryo of the Gramineæ, A. BURGERSTEIN (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 2, pp. 47-60, pl. 1).—This article discusses observations and results of experiments especially covering (1) the mechanical function of the first leaf sheath of cereals; (2) the mechanics of the unfolding of the radicle of cereals and legumes; (3) the abnormal germination of awned grass seeds; and (4) the mechanical function of the trichoma in the appearance of the Coleorrhiza. The grasses studied were *Lolium perenne*, *L. italicum*, *L. westerwoldicum*, *Poa pratensis*, *Arrhenatherum elatius*, *Alopecurus pratensis*, *Agrostis stolonifera*, *A. pratensis*, *Avena flavescens*, *Cynosurus cristatus*, *Dactylis glomerata*, *Festuca ovina*, *F. pratensis*, *F. rubra*, and *Holcus lanatus*.

New strains from the Alpine forms of pasture grasses, T. VON WEINZIERL (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 7, pp. 790-820, pls. 10,

figs. 2).—In this article the author gives his experience and the results obtained from about 20 years' experiments in the breeding of grasses, the principal ones being *Agropyrum caninum*, *Arrhenatherum elatius*, *A. bulbosum*, *Avena pubescens*, *Dactylis glomerata*, *Festuca arundinacea*, *F. pratensis*, *F. rubra*, *Lolium perenne*, *Poa serotina*, *Phleum medium*, *P. michelii*, and *Sanguisorba dodecandra*.

These grasses were greatly improved in yield of forage and of seed over the original strains, as well as over those produced from seed obtained on the open market. In some cases the yield of seed from the improved strains reached over 20 times that of the original forms, and the fodder was increased 10 times in other cases, with a general improvement in quality. It is noted that after the fourth year of breeding the seed yield again declined, due apparently to the close breeding.

On the changes in the composition of the red clover plant during different vegetative periods, E. HASELHOFF and ST. WERNER (*Landw. Jahrb.*, 44 (1913), No. 4, pp. 651-68).—In the work here reported Russian, northern French, southern French, and Hungarian clovers were used. Investigations were made of the plants when young, shortly before flowering, when in full flower, and at the end of the flowering stage.

It is stated that the Russian clover yielded more than the other sorts. With the advance of growth the proportion of leaf decreased, showing a corresponding increase in stem. There seemed to be little difference in the content of organic substances between any of the varieties. In mineral matter the Russian variety contained less calcium and magnesium but more potassium and phosphoric acid than the other 3 kinds. In general the leaves contained a higher percentage of nitrogenous substances and the stems a higher percentage of crude fiber. With increased age of the plants the content of protein substances, ether extract, and minerals decreased, while that of the crude fiber increased.

The greatest elaboration of organic substances seemed to take place during the second and third periods of observation; that of the protein substances took place at a slightly earlier stage, that of the fats later, while that of the nitrogen-free extract matter and crude fiber continued throughout the entire vegetative period. The increase in percentage of mineral matter ceased during the flowering stage and later declined. In the leaves the formation of organic matter, protein, and fat had ceased at the flowering stage, while in the stems elaboration continued somewhat later. The content of crude fiber in the stems was found to be greatest usually by the time the flowering stage was reached, while in the leaves it continued to increase to the end of the growing period. The increase of mineral matter in both stems and leaves was practically ended at the flowering stage. In the young plant the organic matter was chiefly in the leaves, in the older plants it was more in the stems, and toward the end of the vegetative period it was again found to be mostly in the leaves. Nitrogen and fat were found chiefly in the leaves. The nitrogen-free extract matter and crude fiber were principally in the leaves of the young plant, but in the older plant seemed to be stored in the stems. The same was generally true of the mineral matter. Calcium, magnesium, and phosphoric acid were chiefly in the leaves and potassium in the stems.

Data on yields and analyses are given in tabular form.

Trials with different strains of red clover at Svalöf, 1907-1912, H. WITTE (*Sveriges Utsädesför. Tidskr.*, 23 (1913), Nos. 1, pp. 51-64; 2, pp. 91-117).—This gives results of trials of wild red clover (*Trifolium pratense spontaneum*), cultivated red clover (*T. pratense sativum*), European red clover (*T. subnudum*), early red clover (*T. pratense præcox*), late red clover or single cut clover (*T. pratense serotinum*), and American red clover (*T. pratense ex-pansum*). Swedish late red clover as a rule gave more satisfactory yields than

any other strain, either of native or foreign origin. The yield of 2 years' cropping of Swedish late was 58,730 kg.; of Swedish medium 56,570 kg.; and of Swedish early 49,500 kg. per hectare of green material.

The corn crops, E. G. MONTGOMERY (*New York, 1913, pp. XVII+347, figs. 121*).—This is a volume of the Rural Text-book Series, edited by L. H. Bailey, and treats of the production of corn and sorghum crops.

The author divides the subject of the study and philosophy of crop production into 4 phases, the first 2 of which, viz, (a) the plant, its structure, physiology, and normal requirements, and (b) a general survey of the region where it is proposed to cultivate the plant, in order to note how the natural conditions found correspond to the needs of the plant, are of a technical nature. The other 2 phases, (c) the adaptation of the plant to natural conditions on the one hand, and the adaptation of soil to the needs of the plant on the other, and (d) the necessity of protection against other indigenous plants, fungus diseases, and insects, are more practical and written in a more popular style.

Report of the work in corn pollination, III, M. L. FISHER (*Proc. Ind. Acad. Sci., 1911, pp. 283, 284*).—This reports work in continuation of that begun in 1908 and previously noted (*E. S. R., 28, p. 831*).

Some results of hand pollination were as follows: "The effect of using Reid Yellow Dent as a male on Boone County White was to increase the height of the stalk noticeably, while the reciprocal crops showed a sturdier stalk than is usual with either variety. Sweet corn as either parent induced an abundance of suckers. The average for 6 different rows in which the seed used had some sweet in it was 47.5 per cent of the stalks being suckers, some stalks having as many as 6 to 8. Also, where Reid Yellow Dent was the male, the percentage of suckers was large, amounting to 42.6 per cent of all the stalks, while the reciprocal gave only 9.6 per cent. It is well known that sweet corn normally produces many suckers, and under favorable conditions Reid Yellow Dent produces more than most dent varieties. The Sweet-Reid Yellow Dent and the Reid Yellow Dent-Boone County White crosses which had the largest percentage of suckered stalks also showed the largest percentage of twin ears and the smallest percentage of barren stalks. It may not be accepted that suckers are an indication of prolificacy, but this series of experiments indicated as much.

"This being the third year of the experiment, the constancy of dominants and recessives would be expected to show itself. Sweet, red, speckled, and white are supposed to be recessive to dent and yellow. In 18 self-pollinated ears from sweet, 15 were pure sweet and 3 mixed white, sweet, and yellow. In 12 ears from speckled seed, 9 were pure speckled, 2 pure yellow, and 1 pure red. In 15 ears from red seed, 13 were pure red and 2 pure yellow. However, in none of the pollinations from white seed was the percentage of pure ears so high, the highest being from the white seed selected from the Sweet-Reid Yellow Dent cross, in which 7 out of 12 ears were pure. In the experiments of 1908 yellow showed itself dominant to all other colors, consequently it would contain not only the dominants but the hybrids and such a condition manifested itself in the various selection from yellow seed. A notable exception was from a row planted with yellow seed from a twin ear. Every self-pollinated ear from this row was pure yellow. From the Sweet-Reid Yellow Dent cross 2 types arose, one with whitish kernels and white cobs, like the original Stowell Evergreen, and the other with yellowish kernels and red cobs. These 2 types were planted in 1911 on the grounds of the horticultural department, Purdue University. The season being backward the crop was not large, but enough was obtained to show that the types were fixed and would breed true."

Cotton and corn variety tests, R. J. H. DELOACH (*Georgia Sta. Circ. 70 (1914), pp. 3*).—Results of 20 varieties of cotton in 1913 showed Wannamaker

Cleveland to be the heaviest yielder, with 1,055 lbs. of lint cotton per acre, which was 37 per cent of the seed cotton yield. Seventy-six bolls of this variety made 1 lb. of seed cotton.

Of 19 varieties of corn Weekley Improved yielded 51.79 bu. per acre, showing 84 per cent of grain on the ear and 144 ears per bushel.

Local fertilizer experiments with cotton in south Alabama in 1913, J. F. DUGGAR, J. T. WILLIAMSON, and L. J. HAWLEY (*Alabama Col. Sta. Bul. 174* (1913), pp. 147-192).—Continuing previous work (E. S. R., 29, p. 335), the results showed that in 10 out of 23 conclusive experiments, cotton-seed meal was more effective than either acid phosphate or kainit. In 65 per cent of the experiments, acid phosphate was needed to a greater or less extent, while in 70 per cent kainit was needed to a greater or less extent.

The data also show that, as a rule, the complete fertilizers were more profitable than fertilizers applied singly or in pairs. In general it was more effective in all 3 years to apply 200 lbs. of kainit in a complete fertilizer than to use 100 lbs., although in 1911 a larger profit was made when 100 lbs. of kainit was used. The average of the conclusive experiments in both 1912 and 1913 showed that 200 lbs. of cotton-seed meal applied before planting was practically equal in effect to 100 lbs. of nitrate of soda applied after the plants were 6 in. high.

Papers on cotton (*West Indian Bul.*, 13 (1912), No. 1, pp. 1-55).—The following papers were read before the West Indian Agricultural Conference at Port-of-Spain, Trinidad, in January, 1912: The Results of the Cultivation of Cotton in St. Vincent, by W. N. Sands (pp. 1-10); The Cotton Industry in the Leeward Islands, by H. A. Tempany (pp. 11-13); The Cotton Industry in Barbados, by J. R. Bovell (pp. 13-21); Cotton Selection in Montserrat, The Manner of Cross-Pollination of Cotton in Montserrat, and Sakellarides Cotton in Montserrat, by W. Robson (pp. 22-28); The Cotton Boll Weevil, and Notes on Certain Cotton Pests, by H. A. Ballou (pp. 29-38); Outline of Manurial Experiments on Cotton in Tobago, by J. De Verteuil (p. 39); and Cotton Experiments in British Guiana, by J. B. Harrison (pp. 40-55).

Color correlation in cowpeas, W. J. SPILLMAN (*Science, n. ser.*, 38 (1913), No. 974, p. 302).—This gives some observations made in genetic investigations with cowpeas.

"The flower color, which is due to an anthocyan. and the anthocyan in stems and leaves are dependent on 2 Mendelian color factors, one of which, apparently an enzym, is the general factor for color in the seed coat of the cowpea. The other is the special factor for black, which when added to a variety having coffee-colored seeds converts the seed color to black. [The author has] found 3 independent Mendelian factors for 'eye' in the cowpea which, singly and together, give 5 distinct types of 'eye.' One of these factors, which gives the type of 'eye' which [he has] designated the narrow 'eye' also has the effect of inhibiting the development of anthocyan in the flowers, though it permits its development in stems and leaves."

Flax experiments, 1911 (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 3, pp. 515-534).—This article summarizes the results of the flax experimental work in Ireland from 1905 to 1910 inclusive, and reports the continuation of the work for 1911 which was carried on at 10 centers.

Muriate of potash applied at the rate of 1 cwt. per acre increased the yield of straw and fiber to a profitable extent, and the percentage of scutched flax was higher and of better quality than that from the unmanured plats. The combination of muriate of potash and sulphate of ammonia also gave increased yields, but at less profit than the muriate of potash alone. The addition of steamed bone flour did not give satisfactory results in either

increased yields or profits. The results of seed selection showed an improvement in quality and quantity of fiber. Variety tests, including seeds from Russia, are reported in tabular form.

Breeding *Linum usitatissimum* for fiber, N. DJAKONOW (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.)*, 6 (1913), No. 6, pp. 361-374).—Results of breeding flax in 1911 and 1912 in Pskow showed (1) that the height of the plants had little influence on the fiber yield; (2) that the thickness of the stem bore a direct relation to the fiber yield, which increased with the size of the stem; (3) that the maximum yields produced minimum waste products; (4) that with parents having uniformity in thickness of stems the first generation of those high in fiber content were high yielding and those of low yielding parents were low yielding; and (5) that Friebes' method of retting with pure cultures proved satisfactory. This method of retting is described.

The growing of linseed for feeding purposes (*Jour. Bd. Agr. [London]*, 20 (1913), No. 5, pp. 377-385, fig. 1).—In commenting upon the growing of flaxseed as a feed, a discussion is given as to the kinds to sow, the soil, rotation, manuring, chaff, time, method, rate and depth of sowing, cultivation, harvesting, threshing, and value of the straw. The yields of 22 varieties are reported which range from 1,042 to 1,840 lbs. seed and from 1,080 to 3,492 lbs. straw per acre, the length of straw ranging from 10 in. to 3 ft.

The following table shows analyses of flaxseed grown in England from seeds from different sources:

Composition of flaxseed grown in England from different sources.

Constituent.	Calcutta.	Morocco.	Odessa.	Steepe.	Turkey	Berdiansk.
	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>	<i>P. ct.</i>
Albuminoids.....	22.12	23.00	23.50	20.81	22.12	21.56
Oil.....	36.13	38.36	39.65	30.23	35.09	30.26
Soluble carbohydrates.....	18.36	19.49	18.58	17.31	18.65	19.52

The following reasons are given showing why the farmer should grow his own flaxseed: "(1) As a feed for stock it can be grown more cheaply than it can be purchased on the open market, and calves may be more economically reared; (2) it allows of the profitable employment of land which, owing to lateness of the season, can not be sown with spring crops; (3) in a dry early season it can be removed in time to allow of a catch crop being taken."

Report on the manuring of mangels, J. PORTER (*Herefordshire County Council Farmers' Bul.* 8 (1912), pp. 8).—Results are reported which show that top-dressing of mangels with 1 cwt. of nitrate of soda per acre, just after thinning, gave a handsome profit. Nitrate of soda proved more effective than nitrate of lime as a fertilizer, the average yields per acre being 31 tons 16½ cwt. and 29 tons 2½ cwt., respectively. A proprietary fertilizer, analyzing 10½ per cent ammonia and 16 per cent insoluble phosphates, also proved beneficial. The largest yields of mangels and the largest profits were obtained by using the following mixture, applied per acre just before sowing the seed: Two cwt. nitrate of soda in two top-dressings; 1 cwt. sulphate of ammonia; 4 cwt. superphosphate (30 per cent soluble); ¾ cwt. sulphate of potash (48½ per cent potash); and 3 cwt. salt.

Commercial seed potato selection, D. DEAN (*Amer. Agr.*, 92 (1913), No. 13, pp. 3, 4, fig. 1).—This describes the method of selection of seed potatoes on a commercial scale by the author since 1904. The yield of marketable tubers

was the only basis of the hill method of selection used, choice being made by the use of scales. Tubers from high-yielding hills produced 350 bu. per acre as against 70 bu. by tubers from low-yielding hills. Small tubers were found to be unprofitable as seed. Increased yields, improved market qualities, uniformity in maturing, and resulting increased profits are noted as advantages of hill selection of seed potatoes.

The branching of rice, N. NOVELLI (*Staz. Sper. Risicol. Vercelli* [Pub.], 1913, pp. 3-11, figs. 4).—From his experiments and observations the author concludes that this is not a very frequent occurrence, that it is detrimental to the crop, and that it may be caused by irregularity in assimilation, by suppressed vegetative development, or by excessive height of water during stooling.

The economics of paddy planting, N. W. BARRITT (*Agr. Bul. Fed. Malay States*, 1 (1913), No. 12, pp. 443-446).—This article describes the aboriginal methods of rice cultivation and gives the itemized cost of production and value of the product for 2 classes of soil. The estimated cost ranged from \$51.20 to \$91.20 per acre, depending upon the quality of soil and the method employed, while the value of the product ranged from \$60 in the first instance to \$40 in the second or poorer soil. However, it is stated that a family cultivating their own land could be supported for about a year by the labor of 3 persons for from 35 to 65 working days.

The practical significance of the beet leaf, H. PLAHN-APPIANI (*Centbl. Zuckerindus.*, 21 (1913), No. 46, pp. 1678-1680).—This article reviews literature on this subject, and as the results of the author's observations it is noted that the higher the percentage of leaf growth to root the more favorably did the sugar formation in the beet seem to be influenced. The optimum relation varied with the physiological characters and anatomical structure of the leaves of different varieties, which, through the number of stoma and varied activities of the chlorophyll bodies, seemed to cause chemical elaborations differing in degree.

Sugar beets in North Dakota, J. W. INCE (*North Dakota Sta. Rpt. 1912, pt. 1*, pp. 11-28).—This report gives detailed results of cooperative sugar beet culture trials in 1911 and 1912, which include analyses and cultural data as to about 50 samples. A summary of the results of tests since 1891, comprising 385 trials, shows a range of sugar content of from 9.81 to 16.3 per cent, with an average of 12.46 per cent, and a purity coefficient ranging from 74 to 83 per cent, with an average of 76 per cent.

Sugar-beet experiments, 1912 (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 3, pp. 469-480, pls. 2).—This gives the results of cultural experiments in which a method of "molding up" the beets after hoeing gave a better yield of beets with higher sugar content and a higher average coefficient of purity than either ordinary drills or flat cultivation. One hundred and fifty lbs. of nitrate of soda per acre as a top-dressing apparently increased the average yields in the several methods of cultivation, but slightly lowered the content of sugar and impaired the purity of the flat cultivated product. Tabulated results of cooperative experiments with farmers show yields ranging from 1 ton 2 cwt. to 18 tons 14 cwt. per acre, with a sugar content ranging from 15.7 to 19.8 per cent.

Manurial experiments on sugar cane, J. DE VERTEUIL (*Dept. Agr. Trinidad and Tobago Bul. 11* (1912), No. 71, pp. 133-138).—In experiments on 4 estates in which sulphate of ammonia, nitrate of soda, superphosphate of lime, sulphate of potash, bone meal, calcium cyanid, basic slag, and air-slaked lime were used in the production of sugar cane, the best yields, on one estate, 44.83 tons per acre, resulted from the use of 200 lbs. sulphate of ammonia and 100 lbs. sulphate of potash. On another estate 18.39 tons were obtained from the use of

200 lbs. basic slag and 200 lbs. nitrate of soda; on the third 25.39 tons from 400 lbs. calcium nitrate and 100 lbs. superphosphate of lime; and on the fourth 30.83 tons from 200 lbs. sulphate of ammonia, 100 lbs. bone meal, and 50 lbs. sulphate of potash. Analyses are given of the cane juice from 2 of the estates.

Sugar cane in South Africa, H. J. CHOLIS (*Agr. Jour. Union So. Africa*, 5 (1913), Nos. 2, pp. 188-204, fig. 1; 3, pp. 405-418; 4, pp. 575-583; 5, pp. 746-753).—The author describes methods of propagation, field operations, etc.

Experiments on manuring tobacco in Hungary, K. KERPELY (*Dohány Njság*, 30 (1913), No. 2, pp. 2-4; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 3, pp. 411-413).—In these experiments improvement in the combustibility of the leaves was noticeable, which was attributed to the use of nitrate of soda in 2 applications, after the first and second hoeings. Lime from sugar factories resulted in increased yields from a soil that contained 0.112 per cent of lime.

Yield and quality in wheat, A. and GABRIELLE L. C. HOWARD and H. M. LEAKE (*Agr. Jour. India*, 8 (1913), No. 2, pp. 128-138, fig. 1).—This compares the advantages derived from wheat growing by hot weather cultivation, which conserves the moisture after the monsoons, with those from drainage, which prevents "water logging" of the soil during the monsoons. The former method increased the wheat yield from 32.02 to 37.89 bu. per acre in 1910, and from 22.9 to 35.41 bu. in 1911, while the method of drainage increased the yield from 15.55 to 34.45 bu. per acre. The large yields were invariably of better quality than the others.

Wheat storage, T. SANDESON (*North Dakota Sta. Spec. Bul.*, 2 (1913), No. 26, pp. 350-352).—Winter and spring wheats stored in bins usually showed a continual loss in weight up to 4 years, due to moisture and to wearing off of seed coat in handling. The losses ranged up to 2.54 per cent, but in some cases there was a slight increase in weight. Data on 34 samples are given, in some cases covering 4 years.

The change in weight of grain in arid regions during storage, F. S. HARRIS and G. THOMAS (*Utah Sta. Bul.* 130 (1914), pp. 305-313, figs. 10).—Results of storing wheat and oats in sacks and weighing every month for 2 years show that "contrary to popular opinion, there is a gain of from 2½ to 4½ per cent instead of a loss in the weight of grain during the fall after harvest. While this holds for Cache Valley, Utah, other conditions would probably not give just the same results. . . . The method of raising or harvesting grain did not seem to have as much effect on the change in weight as the temperature and humidity. In every case there was a gain in weight during the winter, and a loss during the summer, but the grain weighed less at threshing than at any time later."

Salting Canada thistles, A. J. BLACKMAN (*Breder's Gaz.*, 64 (1913), No. 8, p. 311).—This describes a successful method of eradicating this weed by the application of salt to the plant while it is moist with dew or rain.

HORTICULTURE.

Making special crops pay, D. UTTER (*New York, Springfield, Mass., and Chicago*, 1913, pp. 60, pls. 16, figs. 2).—A practical treatise on the culture of the more important truck crops.

Truck crops for south Mississippi, E. B. FERRIS (*Mississippi Sta. Bul.* 163 (1913), pp. 24).—In order to show the results to be expected from growing various fruits and vegetables on the cut-over lands of south Mississippi, the author here summarizes the results that have been secured from experiments made at the McNeill substation.

Investigations in growing and picking cucumbers, I. K. KORNAUTH and F. ZANLUCHI (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 11-12, pp. 1025-1043).—This is the first report on investigations being conducted under the direction of the Vienna station for plant protection relative to methods of growing and preserving cucumbers. The data here reported deal principally with fertilizer tests and tests of different processes for pickling cucumbers.

Cultural experiments with truck crops: Experiments with garden peas from 1909 to 1912, inclusive, W. SCHULTZE (*Arb. Deut. Landw. Gesell.*, No. 253 (1914), pp. 69).—Tabular data are here given and discussed showing the results secured in cooperative tests of a number of varieties of peas grown for the canning factory.

Polymnia edulis, R. DE NOTER (*Jardin*, 28 (1914), No. 647, p. 36).—A cultural test made in 1912 of the "Poire de terre Cochet," or Yacon (*P. edulis*) of the Andes region of South America leads the author to conclude that although this plant was rejected some 50 years ago as a substitute for the Irish potato, it may prove of more value than the Jerusalem artichoke for French conditions. The tubers are prolific, of an agreeable flavor, and are as readily lifted from the soil as a clump of dahlia tubers, which they closely resemble. Moreover, the foliage appears to have value as a fodder crop.

Cold storage of fruit and vegetables, L. A. BOODLE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, No. 1 (1914), pp. 11-16).—A review of Hill's investigation relative to the respiration of fruits and growing plant tissues in certain gases, with reference to ventilation and fruit storage (*E. S. R.*, 29, p. 538).

Annual report of the South Haven Experiment Station, F. A. WILKIN (*Michigan Sta. Rpt. 1913*, pp. 179-182).—A brief statement is given of variety tests of fruits and nuts at the station, together with some data secured in 1913 on a comparative test of sod mulch and cultivation started in 1907 in blocks of European plums, Japanese plums, and apples. The results indicate a difference in growth in favor of the cultivated trees which is becoming more evident every year.

With reference to spring frost injury to fruits in 1913, apples were not materially injured and the difference, if any, in the effect on varieties was very slight. Of the pears Bartlett suffered most and of the peaches Smock, Salway, and Kalamazoo were most affected. There was apparently no difference in the effect of frost on the varieties of cherries and plums.

Summary of the results at the horticultural experiment station, J. M. STEINBRECH (*Wyo. Bd. Hort. Spec. Bul.*, 1 (1914), No. 4, pp. 30-37).—Notes are given on varieties of fruits, arranged in the order in which they rank, which have been tested at the experiment station at Lander, Wyo.

[New varieties of fruit], N. E. HANSEN (*South Dakota Sta. Rpt. 1912*, pp. 32-34).—The author briefly describes the following varieties of fruit, together with one rose, which have resulted from the plant breeding experiments at the station and were introduced in the spring of 1912: Tokata, Kahinta, Oziya, and Teton plums, the Champa sand cherry and Cikana plum-sand-cherry, the Amur crab apple, and the Ohta raspberry; and the Tetonkaha rose.

Winter spraying with solutions of nitrate of soda, W. S. BALLARD and W. H. VOLCK (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 5, pp. 437-444, pls. 2).—In the course of their investigations on the control of apple powdery mildew in the Pajara Valley, Cal., the authors found that certain crude oil emulsions used as dormant sprays had a marked effect in stimulating an increased vigor of the trees the following spring. As a result it was decided to try the effect of a strong solution of nitrate of soda as a winter or dormant spray.

On February 2, 1912, seven 12-year-old Yellow Bellflower apple trees were sprayed with a mixture composed of 50 lbs. of nitrate of soda, 7 lbs. of caustic

potash, and 50 gal. of water, the caustic potash being added to give the spray an insecticide value. About 7 gal. of spray were applied to each tree so that all of the small twigs were drenched. A check row of trees received no winter spraying and several rows of 7 trees each received various applications of crude oil emulsions and soaps. Likewise, to gain some idea of the effect of nitrate of soda used as a fertilizer, 50 lbs. were worked into the soil under one vigorous tree selected from the row adjoining the nitrate sprayed row. By April 7, the trees in the row sprayed with nitrate of soda and lye were well in bloom while those in the check row adjoining and in the remainder of the unsprayed orchard showed only an occasional flower fully opened. When the check row had reached full bloom the row sprayed with a solution of nitrate of soda and lye was practically out of bloom. At first there was relatively little difference in the advancement of the foliage of the sprayed and unsprayed branches. Later in the spring, however, the sprayed trees assumed a more vigorous, green appearance than the check trees. The tree which received 50 lbs. of nitrate of soda applied to the soil showed no greater vigor than the check trees.

The trees received essentially the same treatment during the summer and were practically free from insect pests. The 7 winter nitrate-sprayed trees produced a total of 40 boxes of apples as compared with a total of about 8 boxes for the check row of 7 trees. The single tree which received the 50 lbs. of nitrate as a soil fertilizer gave no increased yield, whereas none of the trees in the nitrate sprayed row failed to respond.

The experiment was enlarged in 1913 to include other nitrogen-bearing materials as well as potash and phosphoric acid sprays. A frost occurred at the time the fruit was setting which ruined the crop. Data were obtained, however, on the effect of the various sprays on the blossoming of the trees in the spring. Plats sprayed with nitrate of soda at the rate of 1 lb. to a gallon came into bloom earlier than the check trees. This effect was more marked in the cases in which the lye was added to the nitrate solution than when it was omitted. Caustic soda appeared to be just as effective as caustic potash. A solution of nitrate of soda at the rate of $\frac{1}{2}$ lb. to the gallon was less effective and a solution of $\frac{1}{4}$ lb. to the gallon had practically no effect. Nitrate of soda at the rate of 1 lb. to the gallon to which oxalic acid was added in the preparation of 50 lbs. to 125 gal. of solution produced results similar to nitrate of soda plus lye so far as hastening the blooming period was concerned. Lime nitrate, 130 lbs. in 100 gal. of water, and lime cyanid, 92 lbs. in 100 gal. of water, likewise stimulated an earlier blooming of the trees. The effects from sulphate of ammonia were much less marked than those from nitrate of soda. The various nitrogen-bearing fertilizer substances carried relatively the same quantities of nitrogen per gallon. Sulphate of potash had some effect in stimulating an early blooming, but double superphosphate did not. Common salt used at the rate of 68 lbs. to 100 gal. of water produced a distinct effect. Some cooperative experiments were conducted by growers in 1913 on Yellow Bellflower apples, sweet cherries, and pears.

From the results thus far secured in this work the authors conclude that nitrate spraying of normal trees has brought about an earlier blooming in the case of the Yellow Bellflower apple and various varieties of pears sprayed. The results on stone fruits have not been as striking as those on pears and apples. Aside from the effect on crop production there has also been a very noticeable improvement in the color, abundance, and vigor of the foliage. Observations of the original plat of 1912 indicate that the effects obtained by spraying with a solution of nitrate of soda may continue over to the second year. It is suggested that at least under certain conditions some varieties of apples and pears that are more or less self-sterile may have their crop production

materially increased by dormant spraying with solutions of nitrate of soda plus lye. On the other hand, attention is called to the danger of injury from frost that might result from forcing the trees into bloom earlier than normal.

A brief bibliography dealing with the forcing of woody plants is appended.

The pneumatic chisel applied to tree surgery, cutting out cankers, and pruning, G. H. COONS (*Michigan Sta. Rpt. 1913, pp. 173-175*).—The author here describes an adaptation of the pneumatic hammer with chisel attachments which has been found to work very satisfactorily in gouging out cankers, smoothing stubs of branches, and in opening cavities. When used as a substitute for the mallet and chisel the pneumatic chisel has done the work of 4 or 5 men. It is recommended for trial to tree surgeons, park boards and city foresters doing tree surgery work, and to fruit growers with large acreages. The necessary equipment is here described.

Spraying calendar for 1914, P. J. O'GARA (*Off. Path. Rogue River Valley [Oreg.] Bul. 12 (1914), pp. 12*).—This calendar contains concise directions for the control of various insect, animal, and fungus pests of the orchard, field, garden, poultry house, and home. Directions are also given for the preparation and use of insecticides and fungicides.

The practical control of apple diseases and pests, A. L. MELANDER (*Portland, Oreg., [1912], pp. 44*).—A popular spraying manual dealing with the identification and control of apple diseases and pests.

Apple orchard experiments, W. R. BALLARD (*Maryland Sta. Bul. 178 (1913), pp. 58, figs. 24*).—In the first part of this bulletin the author describes experiments which have been conducted in the station orchard. The larger part of the bulletin consists of a revision and extension of a previous station bulletin upon apple culture with special reference to Maryland conditions (E. S. R., 23, p. 242).

In the station orchard, which was planted in the spring of 1889, northern-grown varieties have been compared with those produced in Maryland nurseries. No striking variation has been noted in the growth or in the productiveness or quality of fruit of trees from different sources.

A test was started in 1901 in which the following treatments were included: Sod mulch, clean culture followed by a cover crop, and clean culture throughout the season followed by rye as a winter crop. This plan was continued until the orchard was removed in the spring of 1913. The effect of these treatments on the trees was not marked, except that the foliage on the sod plats turned light green earlier in the fall. There was little difference in the quality of the fruit, the sod plat being fully equal to the other plats. The author points out that the soil was of such a nature as not to be easily affected in dry seasons. Notes are given on varieties grown in the station orchard with reference to their behavior in this particular section, together with a table showing the blooming records of the varieties arranged in the order of their first bloom.

In connection with the cost of growing an apple orchard the statement of E. P. Cohill in the previous bulletin on apple culture has been extended to show the cost of starting and maintaining a 30-acre orchard for a period of 11 years. Although the orchard shows a deficit for the first 7 years, at the end of the eleventh year a net profit of nearly \$30 per acre per year was realized.

Seedlessness in apples as a result of the climatic conditions of Imperial Valley, California, C. NICHOLS (*Univ. Cal. Jour. Agr., 1 (1913), No. 5, pp. 9-11, figs. 2*).—The author calls attention to the prevalent seedlessness of apples and of some of the varieties of pears grown in the Imperial Valley. This phenomenon is attributed to the fact that they come into bloom when the weather is extremely hot and dry, consequently the pistils of the flowers dry up before the pollen reaches and has a chance to fertilize them, or it is pos-

sible that the hot dry weather shrivels and devitalizes the pollen, rendering it incapable of properly fertilizing the pistils. The fact that the apples proceed to develop without pollination is attributed to the extraordinary vigor of growth in the Imperial Valley.

The composition of irrigated and nonirrigated apples, J. S. JONES and C. W. COLVER (*Jour. Agr. Sci. [England]*, 5 (1913), No. 4, pp. 424-428).—In this paper the authors summarize the results secured with apples in their study of hardy fruits growing in both irrigated and nonirrigated sections (E. S. R., 29, p. 236).

Peach culture, C. F. NIVEN (*South Carolina Sta. Circ.* 21 (1913), pp. 3-11).—This circular contains popular directions for starting and caring for a peach orchard.

The pollination and fertilization of pear blossoms, E. E. PESSCOTT (*Fruit World Austral.*, 15 (1914), No. 2, pp. 35-38).—In this article the author calls attention to the importance of cross-pollination and the presence of insects for securing abundant crops of pears, and presents data secured in 5 different seasons showing the various pears which bloom concurrently with important varieties grown in Victoria.

The vine in ancient times, R. BILLIARD (*La Vigne dans l'Antiquité*. Lyon, 1913, pp. VIII+560, pls. 16, figs. 181).—An account of the vine and vine husbandry in ancient times, the subject matter being based upon an extensive bibliographical research as well as archeologic explorations in various countries.

In part 1 consideration is given to the paleontology, prehistory, and mythology of the vine; vineyards and wines of antiquity; some vicissitudes of ancient viticulture; economic phases of ancient viticulture; legal phases of the exploitation of the vine in Greece and in Italy; and commerce and uses of wine. In part 2 ancient viticulture is compared with modern viticulture, consideration being given to climate and soil; methods of reproduction; vineyard management; varieties; cultural practices with respect both to soil and vines; insects and diseases; wine pressing; wine making; and storage of wines.

A bibliography of cited literature is included.

Viticulture in the sandy soils of Mexico, J. DE BÁNÓ and M. SANTA-MARIA (*La Viticultura en los Terrenos Arenosos de la Republica Mexicana*. Mexico, 1913, pp. 131, pls. 49).—A practical treatise on the production of table, wine, and raisin grapes, prepared with special reference to extending the industry in the sandy soils of Mexico.

The American cranberry, P. BOODT (*Dept. Landb., Nijv. en Handel [Netherlands]*, *Verslag. en Meded. Dir. Landb.*, No. 6 (1913), pp. 138-156, fig. 1).—A general descriptive account is given of the cranberry and its culture in America, together with an account of the present status of cranberry culture on the island of Terschelling.

Citropsis, a new tropical African genus allied to Citrus, W. T. SWINGLE and MAUDE KELLERMAN (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 5, pp. 419-436, pl. 1, figs. 7).—A botanical study of Engler's subgenus Citropsis which includes the African species of Limonia.

In the light of their own investigations the authors conclude that these African cherry oranges, as they are here called, are related to Citrus rather than to the Asiatic species of Limonia. They have, therefore, raised the subgenus Citropsis to generic rank. Various species of Citropsis are here described.

Some grafting experiments conducted under the direction of the authors show that the Citropsis species can be budded easily and grown well on all the commonly cultivated species of Citrus. One species at least, *Citropsis schweinfurthii*, appears to be well adapted to poor, sandy soils in Florida, hence its

value as an additional stock for oranges is suggested. Although no hybrids of Citropsis and Citrus have been secured as yet, it has been demonstrated that *Citropsis schweinfurthii* will pollinize the flowers of the common lime (*Citrus aurantifolia*) and breeding experiments are now being carried on by using the pollen of Citropsis on as many species of Citrus as possible.

Citriculture in the Philippines, P. J. WESTER (*Philippine Bur. Agr. Bul.* 27 (1913), pp. 71, pls. 21, figs. 22; abs. in *Philippine Agr. Rev.* [English Ed.], 6 (1913), No. 10, pp. 471-492, figs. 9).—A popular treatise on citrus culture with special reference to Philippine conditions. The important phases discussed include geographical distribution and botany, citrus fruits cultivated in the Philippines, recent introductions, propagation, field culture, windbreaks, harvesting and marketing, plant parasites, diseases, and insect pests and their control.

Cacao culture, O. W. BARRETT (*Philippine Agr. Rev.* [English Ed.], 7 (1914), No. 1, pp. 5-15, figs. 4).—A brief popular treatise on cacao culture in which consideration is given to locations, soils, seed selection, transplanting, culture, pruning, harvesting, fermentation, and pests and diseases.

The buddage of cacao, P. J. WESTER (*Philippine Agr. Rev.* [English Ed.], 7 (1914), No. 1, pp. 27-33, pls. 2).—Popular directions are given for shield budding cacao trees.

Manurial experiments on coconuts, 1912-13, J. DE VERTEUIL (*Bul. Dept. Agr. Trinidad and Tobago*, 13 (1914), No. 77, pp. 1-7).—This report deals with the second year's results of the cooperative manurial experiments on coconuts under the control of the Trinidad Board of Agriculture (E. S. R., 29, p. 746).

Studies in Juglans.—I, Study of a new form of *Juglans californica*, E. B. BABCOCK (*Univ. Cal. Pubs. Agr. Sci.*, 2 (1913), No. 1, pp. 46, pls. 12).—The author here describes a new form of walnut, *J. californica quercina*, which has appeared on seven separate occasions among seedlings of at least three different trees of *J. californica*.

In studying the nature and origin of this new form of walnut the following three working hypotheses have been retained: Hybridization, teratology, and mutation. In connection with the hybridization study, seedlings of *J. californica* pollinated with three species of oak have been secured and will be further observed as to their possible hybrid nature. Thus far no definite conclusions are drawn from the investigation.

Multiplication of floral parts in the carnation, C. H. CONNORS (*Amer. Florist*, 42 (1914), No. 1343, pp. 272-275, figs. 16).—A study of the teratology of the carnation as observed in seedling forms resulting from crosses made by D. M. Jobbins at the New Jersey State Station. The variations are discussed under the following headings: Calycanthemy, phyllody, proliferation, petalody of the pistils, and pleiotaxy of the andræcium and petalody of the stamens.

Report on the plantations at Amani (*Pflanzer*, 10 (1914), No. 1, pp. 42-56).—This comprises brief notes on the various economic plants under observation at the Amani testing gardens.

Garden craft in Europe, H. I. TRIGGS (*London and New York, 1913*, pp. XI+332, pls. 16, figs. 295).—The successive chapters of this work, which deals with the development of ornamental gardening in Europe, discuss ancient gardens in Europe, the gardens of the Middle Ages, the Italian garden, French gardens of the sixteenth and early seventeenth centuries, La Nôtre and Versailles, French gardens of the later seventeenth and eighteenth centuries, garden designs in the Netherlands, English gardens of the sixteenth, seventeenth, and eighteenth centuries, German and Austrian gardens, garden design in Spain, and the English landscape school and its influence on the Continent.

A bibliography of selected works on European garden design is appended.

Improvement of school grounds, C. F. NIVEN (*South Carolina Sta. Circ.* 22 (1913), pp. 3-16, figs. 8).—In this circular the author presents two plans for school grounds and gives suggestions relative to laying out the grounds, grading, soil preparation, lawn making, the planting of hedges and trees, development and care of the school and flower gardens, and playgrounds.

FORESTRY.

Field manual of trees, J. H. SCHAFFNER (*Columbus, Ohio, 1914*, pp. 154).—A pocket guide for the identification of trees at any season of the year. The subject matter constitutes a revision and extension of the author's *Trees of Ohio and Surrounding Territory*. The region here considered includes southern Canada and the northern United States to the southern boundary of Virginia, Kentucky, and Missouri, and westward to the limits of the prairie. In addition to the native species, most of the common cultivated exotic trees have been included.

Profitable trees, A. HENRY (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 14 (1913), No. 1, pp. 41-52).—This address delivered before the Irish Forestry Society discusses the adaptation of various exotic trees for commercial planting in Ireland.

Results of cultural experiments with foreign trees in the Royal Forest at Hambach (Jülich district), GERICKE (*Mitt. Deut. Dendrol. Gesell.*, No. 22 (1913), pp. 66-80, figs. 4).—Notes are given on the condition of a large number of American and Japanese species which have been planted at different periods since 1881.

Report on some cultural experiments with foreign timber species in Mecklenburg, VON BRONSART (*Mitt. Deut. Dendrol. Gesell.*, No. 22 (1913), pp. 88-96).—Notes similar to the above are given on a number of foreign timber species growing at Mecklenburg.

Some notes on Swedish forestry, A. C. FORBES (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 14 (1914), No. 2, pp. 304-312, pls. 4).—The author discusses the importance of Swedish forestry, physical features and climate, forest areas and timber species in Sweden, methods of culture and management, and transit and utilization of timber.

Official proceedings of the division of forestry of the Royal Prussian Ministry for Agriculture, Domains, and Forests, 1912 (*Amtl. Mitt. Abt. Forsten K. Preuss. Min. Landw.* [etc.], 1912, pp. IV+47).—A statistical review of the administration, management, and exploitation of the Prussian state forests and domains.

Progress report of forest administration in the Andamans for 1912-13, J. L. BAKER (*Rpt. Forest Admin. Andamans, 1912-13*, pp. III+36).—This is the customary report on the administration of the state forests of the Andamans, including a financial statement for the year ended June 30, 1913. The more important data relative to forest areas, working plans, forest protection, miscellaneous work, revenues, yields, etc., are appended in tabular form.

Annual progress report on forest administration in the Province of Bihar and Orissa for the year 1911-12, H. H. FORTEATH (*Ann. Rpt. Forest Admin. Bihar and Orissa, 1911-12*, pp. 2+16+XXXIV+2+3).—This statistical report, corresponding to the above, relates to the administration of the state forests in the Province of Bihar and Orissa for the year 1911-12.

Progress report of the Forest Research Institute for the forest year, 1912-13, H. S. HOLE (*Rpt. Forest Research Inst. [Dehra Dun], 1912-13*, pp. 33).—This comprises a progress report of investigations in silviculture, forest

botany, forest economy, forest zoology, and forest chemistry. Lists of recent publications and of all publications issued since the institute was established are appended, together with summaries of the projects being conducted and a financial statement for the year.

Forest seed investigations, 1911-12, J. RAEN (*Mitt. Deut. Dendrol. Gesell.*, No. 22 (1913), pp. 273-280).—Germination tests of both coniferous and deciduous species, secured from various countries, are here reported.

Effect of "Johannistriebe" upon the formation of annual rings, H. L. SPÄTH (*Mitt. Deut. Dendrol. Gesell.*, No. 22 (1913), pp. 118-144, figs. 20).—A summary of the principal results secured in the author's studies of second growth phenomena (*E. S. R.*, 28, p. 340).

The cedar (*Juniperus virginiana*) at Stein-Nuremberg, R. FERLING (*Mitt. Deut. Dendrol. Gesell.*, No. 22 (1913), pp. 84-88, figs. 3).—The author here describes a 35-year-old red cedar plantation of about 15 acres in extent which was set out by L. von Faber to determine the adaptability of the species to German conditions, with special reference to the pencil industry. The growth performance to date appears to warrant the culture of red cedar, both as a forest tree and as an ornamental.

Rubber tapping experiments, I, A. ZIMMERMANN (*Pflanzer*, 9 (1913), No. 12, pp. 585-597).—This is the first report on some tapping experiments which are being conducted to determine the effect of different tapping intervals and different planting distances on the yield of rubber.

While no definite conclusions are drawn from the work thus far, the data presented indicate that although relatively higher yields are secured from frequent tapping and close planting these increased yields are secured at a sacrifice to the welfare of the individual trees. As the trees grow older those which are tapped less frequently during the year and are not too closely planted yield the most rubber.

Pricking or tapping, F. G. SPRING (*Agr. Bul. Fed. Malay States*, 2 (1914), No. 6, pp. 146-148).—For the purpose of making a comparison between the pricking and gouge methods of tapping rubber trees 100 4-year-old rubber trees in the Kwala Lumpur Government plantation were selected, 50 trees being tapped with the Northway pricker and 50 trees with a gouge knife.

The results show in general that, whereas the yield is about the same for either method, the pricking method of tapping is much more expensive and the proportion of expense is apt to increase as the trees increase in girth. Examination of the trees one year after cessation of tapping showed a satisfactory bark renewal on the trees which had been pricked.

The preparation of plantation rubber, S. MORGAN (*London*, 1913, 2. ed., pp. XII+269, pl. 1, figs. 7).—This book, which is offered as a reference work for practical planters, embodies much of the work undertaken on behalf of the Rubber Growers' Association by C. Beadle and Stevens during the first three years after the organization of the Malaya Research Fund. It also contains the work conducted by the author in the Malay Peninsula during that period.

The subject matter is discussed under the general headings of field operations, factory operations, machinery and buildings, the finished rubber, and general discussions.

The preservation of wood, A. J. WALLIS-TAYLOR (*Jour. Roy. Soc. Arts*, 62 (1914), No. 3196, pp. 286-315, figs. 12).—A review of our knowledge relative to the various treatments and processes employed in wood preservation.

About the value of wood-preserving substances containing fluorin, K. KROEMER (*Landw. Jahrb.*, 43 (1912), *Ergänzungs*b. 1, pp. 173, 175).—A study of the disinfecting properties of silicofluoric acid, zinc silicofluorid, copper silic-

fluorid, kronoleum, antorgan, and a proprietary preparation consisting of silico-fluoric acid and zinc silicofluorid. A 3 per cent solution of silicofluoric acid was found to be more effective than a 3 per cent solution of kronoleum and antorgan or a 1 per cent solution of copper silicofluorid and zinc silicofluorid.

A siliceous wood preservative (*Sci. Amer.*, 108 (1913), No. 18, p. 401).—The Marr process consists in impregnating wood for the purpose of preservation with infusorial or diatomaceous earth suspended in paraffin and naphthalene for 4 hours. The advantage claimed over the paraffin-naphthalene process is that it penetrates the wood to the core. The mixture costs but 3 cts. per pound, and less than 2 lbs. are necessary per cubic foot of timber.

The artificial protection of wood with corrosive sublimate (kyanization), F. MOLL (*Ztschr. Angew. Chem.*, 26 (1913), No. 67, Aufsatzteil, pp. 459-463, figs. 6).—A historical review of the utilization of corrosive sublimate in the preservation of wood, together with a description of some modern kyanization plants.

DISEASES OF PLANTS.

Some little known but destructive diseases reported, L. CAESAR (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), p. 28).—The author briefly describes raspberry yellows, a gooseberry disease said to be due to an undetermined fungus which enters the canes through openings made by insects, the mosaic disease of tomatoes, and a disease of pine branches due to a species of *Peridermium*, probably *P. cerebrum*.

The raspberry yellows is characterized by the curling and crumpling of the leaves, and plants that are attacked should be dug out and burned, as they are worthless. The presence of the mosaic disease of tomatoes may be recognized in the mottled appearance of the leaves, dark and light areas alternating. The causes of these troubles have not been determined.

[Report on plant diseases, 1911], JOHANNA WESTERDIJK (*Phytopath. Lab. "Willie Commelin Scholten" Jaarver. 1911*, pp. 21, pls. 2).—Besides brief mention of publications issued, notes are given of studies on diseases affecting beets, potatoes, onions, clover, etc., with treatments employed or suggested.

[Report on plant diseases, 1912], JOHANNA WESTERDIJK (*Phytopath. Lab. "Willie Commelin Scholten" Jaarver. 1912*, pp. 5-23).—This report, continuing that above noted, deals also with diseases of cucumbers, cress, orchard trees, etc.

[Observations on plant diseases], O. SCHINDLER (*Ber. K. Lehranst. Obst u. Gartenbau Proskau*, 1912, pp. 49-51, fig. 1).—Brief notes are given regarding a severe attack of *Monilia* on plum trees; on American gooseberry mildew attacking severely the more highly bred German gooseberry, the American varieties proving nearly immune thereto; and on leaf curl of peach.

[Plant injuries and diseases], R. EWERT (*Ber. K. Lehranst. Obst u. Gartenbau Proskau*, 1912, pp. 138, 140).—Brief notes are given regarding the direct influence of Bordeaux mixture on the sugar content in the sap of currants, gooseberries, and grapes; *Trichoseptoria fructigena* attacking quinces and apples in Germany; *Phytophthora syringæ* on lilacs; and injuries to vegetation by coal tar vapors.

Another host for *Rhodochytrium*, F. A. WOLF (*Phytopathology*, 3 (1913), No. 6, p. 311).—In addition to the host plants that have been reported for this parasitic alga by Atkinson (*E. S. R.*, 20, p. 550), the author reports having found it upon *Ambrosia trifida*, near Montgomery, Ala.

Nematodes or eelworms, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, No. 9 (1913), pp. 343-351, pl. 1, fig. 1).—Besides a presentation of some general facts of parasitism, the author gives brief illustrated descriptions of the parasitic activity of *Heterodera radiculicola*, *H. schachtii*, *Tylenchus devastat-*

trix, *T. tritici*, *Aphelenchus fragariae*, and *A. olesistus* in relation to various economic plants.

New nematode genera found inhabiting fresh water and nonbrackish soils, N. A. COBB (*Jour. Wash. Acad. Sci.*, 3 (1913), No. 16, pp. 432-444, fig. 1).—Descriptions are given of 26 proposed new genera with a type species for each genus. About 73 per cent of these are found in arable soils in various parts of the world and nearly 50 per cent of them on the Arlington Farm of the United States Department of Agriculture. About 90 per cent are newly discovered forms, the rest resulting from further investigation of forms already described.

The chemical action of copper as used against cryptogamic diseases, E. PRISOVSKI (*Rev. Gén. Sci.*, 24 (1913), No. 21, pp. 787, 788).—This is a theoretical discussion of copper compounds as used against cryptogamic diseases and of the chemical processes involved, including the influence thereon of carbonic acid, ammonia, etc., in the air.

Cereal diseases and injuries in 1912, E. RIEHM (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 4-7, pp. 81-107).—This is a very condensed review of contributions appearing in 1912, dealing with animal and other injuries, also parasitic and nonparasitic diseases of cultivated cereals and some uncultivated plants.

An extensive bibliography is appended.

Fungi causing foot rot of cereals in France, A. PRUNET (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 22, pp. 1079-1081).—The author states that foot rot or stalk disease of cereals, which is spreading in France, is caused ordinarily by one or more of three different fungi, *Ophiobolus graminis*, *O. herpotrichus*, and *Leptosphaeri herpotrichoides*, superficially much alike.

A disease of forage plants, P. BERTHAULT (*Bul. Soc. Agr. France*, 1913, Dec. 1, pp. 283, 284, fig. 1).—This is a brief discussion of *Pseudopeziza medicaginis*, which is said to have shown recently a tendency to cause serious damage to crops of alfalfa, clover, and sainfoin in parts of France.

Influence of artificial infection with dry rot on the sugar content of beets, L. GARBOWSKI (*Abs. in Bl. Zuckerrübenbau*, 20 (1913), No. 11, pp. 165, 166).—Contact of sound beets with portions of diseased ones is said to have resulted in very small differences in the sap as regards sugar content. The amount is thought to have been due largely to infiltration and to wounding of the roots employed.

Report on clover canker, E. HAACK (*Illus. Landw. Ztg.*, 33 (1913), No. 23, p. 218, figs. 2).—The author reports, from his district on the west side of the Rhine, severe damage from clover canker in 1913, preceded by dry summers in 1911 and 1912 with heavy precipitation in the fall of the latter year. A few varieties named were not seriously affected.

Cucumber rot, O. F. BURGER (*Florida Sta. Bul.* 121 (1914), pp. 95-109, figs. 6).—This is a detailed account of the author's investigations on the bacterial disease of cucumber, a preliminary report of which has been noted (*E. S. R.*, 30, p. 149).

In addition to describing the disease and its cause, the author gives an account of spraying experiments in which Bordeaux mixture was used for the control of the disease, and it was found that on thoroughly sprayed vines 17 per cent of the cucumbers were affected with the disease as compared with 35 per cent on the sprayed vines. In other experiments it appeared that irrigation and the application of nitrate of soda to cucumbers rendered them more susceptible to the trouble.

Diseases of flax, W. DALLIMORE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, No. 9 (1913), p. 335).—The author mentions as rather troublesome at times in

England, flax wilt (*Fusarium lini*) and flax rust (*Melampsora lini*), recommending for the former continual rotation of crops.

Report of the professor of botany, J. E. HOWITT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 29-33).—The author investigated a number of ginseng gardens and found that the most serious diseases in Ontario are the *Alternaria* blight (*A. panax*), rust, fiber rot or end rot (*Thielavia basicola*), and a soft rot due to bacteria. These diseases are briefly discussed and, so far as definitely known, methods of prevention are indicated.

A method of treatment for mushroom root rot, H. P. BARSS (*Oreg. Countryman*, 6 (1913), No. 3, pp. 113-115, figs. 2).—Among the remedies recommended for this disease of fruit trees, due to *Armillaria mellea*, are the removal of all affected or dead roots and bark, disinfection with Bordeaux mixture, lime sulphur, corrosive sublimate solution, etc. After surgical treatment exposed surfaces should be protected with tree paint or grafting wax.

Fusarium leaf roll of potatoes, W. HIMMELBAUR (*Umschau*, 17 (1913), No. 50, pp. 1046, 1047, figs. 7).—This is a somewhat popular and partly graphical presentation of data, most of which have been noted previously (E. S. R., 28, p. 848).

Potato wilt, leaf roll, and related diseases, W. A. ORTON (*U. S. Dept. Agr. Bul.* 64 (1914), pp. 48, pls. 16).—On account of the confusion which exists among plant pathologists and others concerning a number of potato diseases commonly referred to as wilt, leaf roll, leaf curl, *Fusarium* blight, bacterial ring disease, etc., the author has undertaken to bring together the information relating to these diseases in order that they may be more readily differentiated.

The principal diseases discussed in this bulletin are the *Fusarium* wilt, due to *F. oxysporum*, which is said to be widespread in America, but not yet recognized from Europe; the *Verticillium* wilt, caused by *V. albo-atrum*, present both in America and in Europe; the leaf roll, which is considered an inheritable disease but probably not due to a parasite and which is common in Europe and has lately appeared in America; the curly dwarf, an inheritable, nonparasitic disease, found both in Europe and in America; the rosette, due to the fungus *Rhizoctonia*, which is very prevalent in the western United States; and the mosaic, which is a pathological condition present both in Europe and in America. These different diseases are described at some length and suggestions given for their recognition, and where known control measures are described. A bibliography is appended.

Influence of temperature on the spread of potato diseases, F. GAUL (*Deut. Landw. Presse*, 40 (1913), No. 92, p. 1094).—Referring to observations previously reported by Voges (E. S. R., 30, p. 541), the author states his belief that the drop in temperature from 14.5 to 10.3° C. about August 27, 1912, was largely instrumental in checking the progress of *Phytophthora* and in giving a fair crop of sound tubers notwithstanding the wet weather prevalent about that time.

Diseases and pests of the sugar beet in Bohemia and of the crops used in rotation, 1911, H. UZEL (*Ztschr. Zuckerindus. Böhmen*, 38 (1913), No. 3, pp. 133-140, figs. 2).—A brief account is given of observations made at the phytopathological section of the experiment station for the sugar industry at Prague for 1911, including notes on heart rot, dry rot, red rot due to *Rhizoctonia violacea*, etc., and a formation of teratological character affecting beets; also on *Puccinia glumarum* and *Urocystis occulta* on rye, nematodes attacking oats, and other animal pests on various crops employed in rotation.

Red rot of sugar cane, E. J. BUTLER and A. HAFIZ (*Mem. Dept. Agr. India, Bot. Ser.*, 6 (1913), No. 5, pp. 151-178, pl. 1).—This is in pursuance of previous reports by Butler (E. S. R., 18, p. 450; 19, p. 162) on red rot of sugar cane in

India due to *Colletotrichum falcatum* and held to be identical with the form attacking the leaves and stalk as noted in Louisiana by Edgerton (E. S. R., 26, p. 548).

It is stated that spread of infection from growing canes is rather unlikely in the absence of insect parasites, but that from dead and rotting canes the fungus may be carried to sound ones by soil or irrigation water, by the feet of workmen, or by the cane fly (*Pyrilla aberrans*). The fungus is said to enter the plant most readily at the eye, but leaves, stems, and shoots may be attacked, producing typical symptoms. Wounds also favor its entrance. Much of the damage by this fungus is due to inversion of cane sugar owing to the presence of invertase, which has been demonstrated both in the fungus and in the nutritive medium.

The disease is said to be less severe on the lighter canes. Care in selection to secure only sound cane, removal of plants showing infection, and long period rotation are preventive measures suggested.

Some new sugar cane diseases, E. J. BUTLER and A. HAFIZ (*Mém. Dept. Agr. India, Bot. Ser.*, 6 (1913), No. 6, pp. 181-208, pls. 6, fig. 1).—Continuing the above report on sugar cane diseases the authors describe three fungi. One associated with a cane wilt is named *Cephalosporium sacchari* n. sp. A second found in a collar rot is named *Hendersonina sacchari* n. g. and sp. A third, said to cause a leaf spot or streak, is named *Helminthosporium sacchari* n. sp. These are not known to cause much loss at present, but further investigations are in progress.

The importance of the tarnished plant bug in the dissemination of fire blight in nursery stock, V. B. STEWART (*Phytopathology*, 3 (1913), No. 6, pp. 273-276, pl. 1).—In a previous publication (E. S. R., 29, p. 348) the author called attention to the rôle of various insects in the dissemination of fire blight in nursery stock. The investigations previously described have been continued, and some experiments are reported on the tarnished plant bug (*Lygus pratensis*), which appears to be the most important insect in transmitting the blight to healthy trees.

In these experiments tarnished plant bugs were transferred from infected trees or were placed in contact with cultures of the organism and then transferred to sound trees. The results of the experiments make it evident that the tarnished plant bug is able to transmit the casual organism of fire blight from exuding blight lesions to healthy shoots.

Apple leaf spot (*Bd. Agr. and Fisheries* [London], Leaflet 281 (1913), pp. 4, figs. 4).—A brief description is given of *Sphaeropsis malorum* attacking the trunk, branches, leaves, and fruit of apple, pear, and quince in the United States and more recently in England.

Removal of dead branches and leaves, and spraying with half strength Bordeaux mixture about a week after the fall of the petals and again about a month later are recommended, as is also treatment with lime-sulphur wash.

Control of apple black rot, F. A. WOLF (*Phytopathology*, 3 (1913), No. 6, pp. 288, 289).—The apple black rot, due to *Sphaeropsis malorum*, is said to be becoming very destructive in certain commercial apple orchards in Alabama, and some experiments were carried on in 1912 and 1913 for its control.

In 1912 the trees were sprayed with lime sulphur, but it proved entirely ineffective against either the black rot or the bitter rot, irrespective of the time and number of applications. In 1913 the experiment was repeated, Bordeaux mixture being used as the fungicide. The first application was made about the middle of July and a second about two weeks later. Satisfactory results were obtained from this work, less than 1 per cent of the variety Champion being affected while from 85 to 90 per cent control was obtained with Black Ben Davis.

It is thought that this amount of loss could have been appreciably reduced had the sprayings been made earlier in the season.

Physalospora cydoniæ, L. R. HESLER (*Phytopathology*, 3 (1913), No. 6, pp. 290-295, pl. 1, figs. 2).—In connection with studies on the New York apple tree canker (*Sphaeropsis malorum*), attempts have been made to determine the parasitism of the fungus, its identity, the possibility of the existence of different strains, and the question of its perfect stage. In the present paper the results of an investigation on the perfect stage of the fungus are given.

Until 1913 unsuccessful efforts have been made to determine the ascogenous form of the fungus. In February some diseased apple twigs were received at the laboratory at Cornell University which later developed the immature ascomycete forms. Subsequent investigations have shown that the ascogenous form is a species of *Physalospora*, and with the data at hand the author is inclined to accept for it the name *P. cydoniæ*.

Rust of apple, N. J. GIDDINGS (*W. Va. Crop Pest Com. Bul.* 2 (1913), pp. 7-11, fig. 1).—This is a brief account of the life history of apple rust, with a discussion of the resistance shown by certain varieties thereto and protective measures studied, emphasizing the destruction of all cedars within a mile or so of apple orchards.

Note on *Plowrightia morbosa*, T. H. MACBRIDE (*Phytopathology*, 3 (1913), No. 6, pp. 311, 312).—The author reports the black knot fungus as universally present in Iowa on all sorts of wild plums but not on *Prunus virginiana* or *P. pennsylvanica*. Recently observations have shown that it also attacks the Juneberry (*Amelanchier canadensis*).

A severe outbreak of apoplexy of grapevines, FISCHER (*Ber. K. Lehranst. Wein, Obst u. Gartenbau Geisenheim*, 1912, pp. 216-219, figs. 2).—Discussing the spatial and other relations of grape stocks previously affected in various degrees, the author states that no stocks planted in 1912 suffered from this leaf scorch disease.

Court-noué in Austria, KOBER (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 51, pp. 779-781).—The author gives some results of observations on court-noué in Lower Austria made during 16 years, as related to stock, elevation, temperature, soil, etc. Along with more specific statements regarding the susceptibility of certain stocks or hybrids, the general conclusion is drawn that this trouble is more common in level vineyards of deep fresh soil, and particularly in those years in which circulation in the vines is checked by cold weather during the spring months.

Treatment for gray rot of grapes, A. MORUCHON (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 51, pp. 776-779).—This is a comparative study of the effects, when used in varying concentrations, of several common fungicides as protective against *Sclerotinia fuckeliana* (*Botrytis cinerea*), causing gray rot of grapes.

A destructive form of white rot of grapevines, A. TÉNÈS (*Bul. Agr. Algérie et Tunisie*, 19 (1913), No. 17, pp. 341, 342).—The occurrence of a disease affecting the petioles and peduncles is noted. The fungus associated therewith is said to be a *Phoma*.

Tests with powdered fungicides against *Peronospora* and *Oidium*, FISCHER (*Ber. K. Lehranst. Wein, Obst u. Gartenbau Geisenheim*, 1912, pp. 18, 19).—Three commercial preparations named are recommended, which are said to prove efficient without causing injury.

The possibility of reaching the underside of grape leaves with sprays, FISCHER (*Ber. K. Lehranst. Wein, Obst u. Gartenbau Geisenheim*, 1912 pp. 15-18, fig. 1).—Illustrated descriptions are given of several forms of nozzles

designed by the makers for the application of sprays to the underside of grape leaves, and their relative merits discussed.

Nematode disease of banana in Egypt, J. LAMBA (*Bul. Union Agr. Égypte*, 10 (1912), Nos. 83, pp. 17-21; 85, pp. 77-86).—Besides a brief account of the progress of the nematode disease noted as threatening the practical extermination of banana culture in Egypt, the author discusses the application and value of several treatments mentioned, such as employment of trap plants and of various insecticides, liquid and gaseous.

Coconut diseases, S. J. ASHEY (*Jour. Jamaica Agr. Soc.*, 17 (1913), No. 11, pp. 20-25).—In this report the author deals with die-back disease ascribed to a *Diplodia* attacking trees aged 15 years and upward; bud rot disease, thought to be identical with *Bacterium lactis aerogenes*; gummosis, ascribed to unsuitable soil conditions; and dwindling or pencil-point, of undetermined cause. Remedies are suggested for the control of the diseases.

Stilbum flavidum, a parasite of coffee and its systematic position, A. MAUBLANC and E. RANGEL (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 19, pp. 858-860; *abs. in Agron. Colon.*, 1 (1913), No. 6, pp. 179-181).—The authors state, as the result of a study of *S. flavidum* found on a considerable number of wild plants, that this parasite, which attacks coffee trees only under favorable conditions of heat and moisture, is the sterile form of a fungus which they have named *Omphalia flavida* n. sp. It is stated also that the parasite readily extends itself without the recurrence of the perfect form.

Black pit of lemon, C. O. SMITH (*Phytopathology*, 3 (1913), No. 6, pp. 277-281, pl. 1).—In continuation of a previous note (*E. S. R.*, 29, p. 650), the author states that for the past three years two of the chief commercial varieties of lemons, the Eureka and Lisbon, have shown the presence of a disease called black-pit. This trouble seems to be increasing and has assumed some economic importance. It develops on tree-ripe lemons during the spring months, and does not reappear during the remainder of the year.

A study of diseased fruits showed the presence of a bacterial exudation, and transfers were made both by punctures and by spraying. Almost without exception, successful inoculations followed the punctures in from 3 to 10 days, and in some instances the disease developed after the fruit was sprayed with the organism.

The organism which is held to be responsible for this trouble, *Bacterium citriputeale* n. sp., is technically described.

On some relations between *Puccinia malvacearum* and the tissues of its host plant (*Althæa rosea*), W. ROBINSON (*Mem. and Proc. Manchester Lit. and Phil. Soc.*, 57 (1913), pt. 3, No. 11, pp. 24, pls. 2, figs. 7).—The author has made a study of the intimate relation which exists between this fungus and the cells of the host, and gives a description of the histological features of the diseased spot as compared with the corresponding normal tissues.

It was found that the germ tube from the sporidium of *P. malvacearum* penetrates the epidermis of the hollyhock, sending an infection vesicle into the cell. Later, branches are produced which grow into the intercellular spaces, and the mycelium sends haustoria into the cells of the affected area. Strands of hyphae were found to pass into the vascular bundles where they set up a definite attack on the phloem region. In the case of the leaf each pustule is related to several vascular strands. According to the author, there was a definite diminution in the quantity of starch in the regions invaded by the fungus, and the cells of the host plant were found to remain alive for a considerable time after the entry of the haustoria. The haustoria lie within the protoplasm and grow toward the nucleus. Various changes in the cell contents were noted on the entry of the haustoria. The chloroplasts lost their color and contour and

finally disintegrated. The nucleus moved from a peripheral position toward the center of the cell. There was also a distinct increase in the size of the nucleus while the chromatin gradually diminished in quantity.

Contributions to a knowledge of "the snap-beech" disease, ELSIE M. PRIOR (*Jour. Econ. Biol.*, 8 (1913), No. 4, pp. 249-263, pls. 2).—The author gives an account of studies made on a fungus disease of beech causing trees to break at a point usually 15 to 20 ft. above ground, the rest of the trunk remaining sound. The disease is attributed to *Polyporus adustus*, which is said to be a wound parasite. An account of its activity in this connection is given. Several enzymes named were present in the mycelium.

Chestnut blight and its control in West Virginia, A. B. BROOKS (*W. Va. Crop Pest Com. Bul.* 2 (1913), pp. 12-16, figs. 2).—This is a brief account of the history, distribution, and attempted control of chestnut blight in West Virginia. Radical sanitary surgery in case of trees valuable for shade, ornamentation, etc., and complete eradication of forest trees affected are measures insisted upon.

The relative prevalence of pycnospores and ascospores of the chestnut blight fungus during the winter, F. D. HEALD and M. W. GAEDNER (*Phytopathology*, 3 (1913), No. 6, pp. 296-305, pls. 3).—A detailed account is given of a study of the dissemination of the pycnospores and ascospores of the chestnut blight fungus, a preliminary account of which has already been noted (*E. S. R.*, 29, p. 351). It was found that viable pycnospores of the chestnut blight fungus are washed down the trees in large numbers during every winter rain, but no ascospores were washed down by the rains during the period covered by the test.

Notes on oak mildew, E. NOFFRAY (*Bul. Soc. Nat. Agr. France*, 73 (1913), No. 6, pp. 474-477).—It is stated that in 1912 the attack of oaks by *Oidium quercinum* appears to have been less severe than in recent years. The American oak (*Quercus palustris*) continues to show greater resistance to attack by this fungus than do the native species.

[Destruction of coniferous seedlings by *Fusarium*], G. LÜSTNER (*Ber. K. Lehranst. Wien, Obst u. Gartenbau Geisenheim*, 1912, pp. 148-150, fig. 1).—A disease of conifer seedlings, causing in a short time a loss of 70 per cent of the plants, is briefly reported upon. The trouble is thought to be due to a *Fusarium*.

Production of secondary sporidia by *Gymnosporangium*, C. H. CRABILL (*Phytopathology*, 3 (1913), No. 6, pp. 282-284, fig. 1).—The author reports observing secondary spores formed by the germinating sporidia of *G. juniperi-virginianæ* while conducting some investigations on the cedar rust in 1913. Secondary sporidia have also been observed by him in *G. clavipes*, and it is thought that probably this phenomenon may occur in other species of *Gymnosporangium*.

Notes on *Cronartium comptoniæ*, II, P. SPAULDING (*Phytopathology*, 3 (1913), No. 6, pp. 308-310).—In a previous publication the author gave some data concerning the eastern pitch pine blister rust caused by the fungus *C. comptoniæ*. This fungus was not thought to be of economic importance, as it seemed at that time to be confined to a number of species of *Pinus* which have little value as timber trees. Later it was observed on *P. ponderosa*, and it is probable that it would prove a serious enemy of that species of pine should it ever be grown in any quantity in the East. *P. sylvestris* is also said to be a host of this fungus.

The introduction of a European pine rust into Wisconsin, J. J. DAVIS (*Phytopathology*, 3 (1913), No. 6, pp. 306, 307).—The author reports the occur-

rence of *Coleosporium sonchi-arvensis* on *Sonchus asper* in Wisconsin. This rust has for its Peridermium host some species of pine.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

A determination of the economic status of the western meadow lark (*Sturnella neglecta*) in California, H. C. BRYANT (*Univ. Cal. Pubs., Zool., 11* (1914), No. 14, pp. 377-510, pls. 4, figs. 5).—This is a more detailed report of studies previously noted from other sources (E. S. R., 29, p. 52). A bibliography of 157 titles is appended.

The western red-tailed hawk.—Has it a money value? H. K. DICKSON (*Univ. Cal. Jour. Agr., 1* (1913), No. 5, pp. 22-24, 33, fig. 1).—This paper includes an account of the habits and economic status of *Buteo borealis calurus*, known in California as the "squirrel hawk". It is estimated that an annual benefit of at least \$18.25 is derived from the destruction of ground squirrels by a single hawk.

A laboratory guide to the study of parasitology, W. B. HERMS (*New York, 1913*, pp. XV+72).—This guide is divided into 3 parts: (1) Medical entomology (pp. 1-44); (2) helminthology (pp. 45-68); and (3) life history studies on living parasites (pp. 69-72).

Thirteenth report of the state entomologist of Connecticut for the year 1913, W. E. BRITTON (*Connecticut Sta. Rpt. 1913*, pt. 3, pp. VIII+181-256, pls. 12).—The first part of this work consisting of financial and organization statements is followed by a discussion of the work of inspecting nurseries, imported nursery stock, and apiaries, and of gipsy and brown-tail moth control.

The importance of *Archips rosana* as a leaf folder on privet is discussed by B. H. WALDEN (pp. 223-226), who reports that this tortricid was the source of injury to many privet hedges in New Haven during May. Notes are given on its life history and habits. The tachinid parasite *Exorista pyste* was reared from the larvæ. The application of arsenate of lead at the rate of 2 lbs. to 50 gal. of water soon after the leaves unfold and removing and destroying the infested tips are mentioned as remedial measures. Mention is next made of the unusual abundance of the apple-tree tent caterpillar, a bulletin relating to which has been previously noted (E. S. R., 29, p. 655). Few complaints were received of injury by white grubs, which were extremely abundant in Connecticut the previous year. *Otiorhynchus sulcatus* was the source of considerable injury to Japanese yew in a nursery at Pomfret through devouring the small roots and girdling the larger ones and the main stem below the surface of the ground.

Field tests in controlling several insects attacking vegetable crops are reported by W. E. BRITTON and B. H. WALDEN (pp. 232-237). In experiments with the cabbage maggot it was found that on new ground plowed in the spring and thoroughly pulverized with the disk harrow cabbage plants about which tar paper disks were placed showed a much lower percentage of infestation than did the check plants. Blackleaf 40 applied August 15 at the rate of 1 teaspoonful to a gallon of water with soap added to act as a spreader destroyed all the cabbage aphids with which it came in contact. In spraying tests of the value of several insecticides in controlling the onion thrips only negative results were obtained, this being due in large part to an inability to penetrate the base of the leaves below the sheath which inclosed the thrips. In spraying tests of insecticides for the pea aphid (*Nectarophora pisi*) blackleaf 40 gave quite satisfactory results.

Attention is called to the fact that in southwestern Connecticut and in adjoining portions of New York State many hickory trees have died during the

past 2 or 3 years and many more have been injured, the hickory bark beetle or bark borer (*Scolytus quadrispinosus*) being the chief cause. Many thousands of trees are said to have been killed in the vicinity of New York City and in Connecticut, particularly in Fairfield County. It is pointed out that since badly infested trees can not recover they should be cut between October 1 and May 1 and burned, as should dead branches and tops of living trees.

The pear midge (*Contarinia* [*Diplosis*] *pyrivor*a), which infested fruit at Cannon Station, Mystic, and Watertown, causing the young pears to drop freely, is briefly considered. The West Indian peach scale (*Aulacaspis pentagona*) was discovered in Greenwich, Conn., on Chinese privet (*Ligustrum ibota*), this being the first record of its occurrence in Connecticut, though collected on different species of *Prunus* at Jamaica Plain, Mass., 15 years previously.

A detailed report of mosquito work (pp. 242-249) in Connecticut in 1913 is followed by a brief discussion of the entomological features of the year, and miscellaneous insect notes. Under the latter heading mention is made of the dying oak trees, flight of spruce bud moth (*Tortrix fumiferana*), parsley stalk weevil (*Listronotus latiusculus*) taken in parsley brought from a vegetable farm in New Haven, the occurrence in Connecticut of the cottony maple scale, *Omphalocera dentosa* which was the source of more damage in 1913 than in any preceding year, the eggs of *Hemerocampa definita* and their resemblance to gipsy moth eggs, cocoons of the Prometheus moth (*Callosamia promethea*), the subsidence of the San José scale, galls which occurred on gooseberry, the cause of which has not been determined, abundance of spittle insects, pupa cells of the clover weevil (*Phytonomus punctatus*), the birch leaf skeletonizer (*Bucculatrix canadensisella*) which having subsided since 1910 is again apparent, the elm leaf beetle (*Galerucella luteola*), the poplar sawfly (*Trichocampus viminalis*) which for several years has been common on Carolina poplars in the vicinity of the station, the linden borer (*Saperda vestita*) which was rather common on young linden trees in one nursery, and the tarnished plant bug which was unusually abundant.

[Report of the] department of entomology, E. S. TUCKER (*Louisiana Stas. Rpt. 1912*, pp. 17-20).—A brief statement is given of the progress made in studies of the principal insect enemies of stored rice and their control.

Collections of rice at New Orleans, Donaldsville, and Crowley have shown as many as 16 species to be implicated in rice infestation. Among the more important of these are the rice weevil, which prefers milled rice, either whole or cracked but also occurs in unbulled grain; the lesser grain borer (*Rhizopertha dominica*), which is the source of the most damage to the rough grain; the Angoumois grain moth, which prefers the rough grain; the cadelle, which does not appear to injure the whole grain but lives in the ground products; and the rust-red flour beetle (*Tribolium navale*), which seems to depend upon crushed or powdered products in which to breed. The cadelle shows a tendency to prey on the more destructive pests and individuals will even devour one another.

Fumigation experiments with carbon bisulphid, hydrocyanic acid gas, and sulphur have shown that the penetration into bags of rice was insufficient to kill insects buried deeply in the grain. Heating rice to a temperature of 120° F. killed all insects but caused the grain to fracture and had to be abandoned. The placing of rice in cold storage through the warm months of the year was found to be an effective means of protecting rice from insects, but due to the expense only the choice grades have been kept in this manner.

In a 14 months' test of several grades of bagging it was found that rice kept in a bag made of fine drilling was slightly infested and damaged; in one made of 8-oz. duck scarcely an insect was found, or evidence of one among its con-

tents; while the grain kept in 10-oz. duck passed through the test in absolutely perfect condition. These tests were carried on surrounded by extreme infestation of grain.

Twenty-eighth report of the state entomologist, 1912, E. P. FELT (*Univ. State N. Y. Bul. 547 (1913), pp. 265, pls. 14, figs. 79*).—Field work with the codling moth was continued (E. S. R., 28, p. 156) and the results of the previous 3 years' work satisfactorily confirmed. Spraying during 1912 was confined to young and moderate-sized Ben Davis trees, a power spray being used. A check or unsprayed tree produced only 38.95 per cent of sound fruit, while sprayed trees yielded from 97.53 to 99.53 per cent of worm-free apples. Another plat similarly treated comprised larger trees and produced from 95.17 to 98.77 per cent of sound fruit. The results are presented in tabular form. In a commercial orchard at Arlington from 97.87 to 98.77 per cent of all the fruit sprayed was worm-free.

"Taking the check or unsprayed trees with their 98,952 apples or approximately 247½ bbls. as the standard, we find that one spraying in the first period reduces the number of wormy apples by 28,150 (70½ bbls.) or end wormy alone by 20,341 apples (50½ bbls.). The one late spraying 3 weeks after blossoming takes 15,854 apples (39½ bbls.) from the wormy column and but 12,546 apples (31½ bbls.) from the end wormy. The 2 sprays, one given just after blossoming and the second about 3 weeks later, reduced the number of wormy apples by 28,686 (72½ bbls.) and the end wormy by 20,441 (51 bbls.). This latter is not very different from the returns given by the first timely application, and in connection with the data for one late spray, shows at once that the latter is comparatively inefficient, so far as controlling codling moth is concerned. The 3 treatments, one spraying just after blossoming, a second about 3 weeks later, and a third the latter part of July, eliminate from the wormy column 30,081 apples (75 bbls.) and from the end wormy 20,458 apples (51 bbls.). . . . The second spraying resulted in a gain of only 1½ bbls., while 3 sprayings produced an additional gain over the 2 of but 2½ bbls., or a total gain over that secured from one application of 4½ bbls. The one late spraying eliminated only 39½ bbls. from the wormy column, a saving of approximately four-sevenths."

In a discussion of the Hessian fly the author reports upon losses in New York State in 1912, parasites, preventive and remedial measures, etc. An account of the fall army worm includes a bibliography of 43 references. In an article on the elm leaf beetle it is pointed out that it will feed upon poisoned foliage only when compelled by hunger and that as a consequence thorough spraying is necessary to secure satisfactory results. Summarized accounts of white grubs and June beetles (*Lachnosterna* spp.), the hickory bark borer (*Eccoptogaster quadrispinosa*), and the pear thrips, their life history, injuries, and control measures, follow.

Experimental investigations of the effect of insecticides on the hickory bark borer are said to give sufficient data to warrant a continuance of the work, particularly with a preparation of oil or carbolic acid for the purpose of destroying the beetles or the recently hatched grubs before they have had an opportunity to bore any distance from the egg chambers.

Studies of the life history of the queen blow fly (*Phormia regina*) show that from 12 to 24 hours are required for the incubation of the eggs, that the first larval stage lasts about 3 days and the second stage 2 to 3 days, while the period of active feeding in the third stage is limited to about 3 days, though the transformation to puparia may not occur until 3 days later. Observations on the Georgian flesh fly (*Sarcophaga georgina*) show that the second larval stage lasts about 4 days and the third stage 3 days, the prepupal condition persisting for about 6 days, the insects remaining in puparia 22 to 23 days.

The conclusions drawn in an article on the use of oils on dormant trees are similar to those in the article previously noted (E. S. R., 29, p. 354).

Under the heading of Notes for the Year the author gives brief accounts of some of the more injurious or interesting species coming to attention. The fruit tree insects include the fruit tree bark beetle (*E. rugulosa*), apple tent caterpillar, resplendent shield bearer (*Coptodisca splendoriferella*), apple leaf trumpet miner, Palmer worm, and pear midge (*Contarinia pruviora*). The forest insects include the forest tent caterpillar, locust leaf miner (*Chalepus dorsalis*), bronze birch borer (*Agrilus anxius*), pine bark borer (*Ips pini*), and pine bark aphid (*Chermes pinicorticis*). Miscellaneous insects include the hawthorn sawfly (*Trichiosoma tibialis*), *Neuroterus saltatorius*, two-spotted lady beetle (*Adalia bipunctata*), two-spotted Anomala (*Anomala binotata*), mosquito control, cotton moth (*Alabama argillacea*), periodical cicada, Juniper bug (*Pentatoma juniperina*), and mite migration.

Lists are given of the publications of the entomologist and additions to collections.

In A Study of Gall Midges which is appended (pp. 127-226) the author gives a systematic descriptive account of the gall midges (Itonididae or Cecidomyiidae) of the subfamilies Lestremiinae and Heteropezinae, of which 11 of the former and 1 of the latter are described as new to science.

Report of committee on common names of economic insects in Hawaii, E. M. EHRHORN, D. T. FULLAWAY, and O. H. SWEZEY (*Proc. Hawaii. Ent. Soc.*, 2 (1913), No. 5, pp. 295-300).—This paper gives a list of the common names of some of the more important insect pests in Hawaii, including 17 species of Hymenoptera, 21 of Diptera, 29 of Lepidoptera, 25 of Coleoptera, 14 of Hemiptera, with the addition of 34 of Coccidae, and 7 miscellaneous species.

Injurious insects in Brazil, G. BONDAR (*Bol. Agr. [Sao Paulo]*, 14. ser., No. 7 (1913), pp. 434-470, figs. 32).—This second paper (E. S. R., 30, p. 454) relates to the insect enemies of fruits belonging to the Myrtaceae, of which 21 varieties are listed as being cultivated in Brazil.

Among the more important species dealt with are the cerambycid beetles *Polyrrhaphis grandini* and *Dorcacerus barbatus*; the buprestid *Conognatha magnifica*; a curculionid borer (*Cratosomus* sp.) a lepidopterous borer (*Stenoma albella*); a geometrid borer (*Siculades fulcata*); a hesperid (*Pyrrhopyge* sp.); several lepidopterous leaf feeders; and several hemipterans (*Pachycoris torridus*, *Capulina jaboticabae*, *C. crateraformans*, *Ceroplastes jancircensis*, and *Aleyrodes horridus*).

The principal insect enemies of grain in central and southern Russia, N. V. KURDJUMOV (*Trudy Poltav. Sel'sk. Khoz. Opytn. Stantsii*, No. 17 (1913), pp. 119, pls. 7, figs. 49).—This report upon the important grain pests of central and southern Russia is accompanied by excellent colored figures of most of the species dealt with.

Report of the zoologist, H. MORSTATT (*Pflanzer*, 10 (1914), No. 1, pp. 36-42).—A brief account of work with insect pests of cultivated plants in German East Africa is included in this report.

Fumigating nursery stock, G. C. BECKER (*Arkansas Sta. Circ.* 19 (1913), pp. 12, figs. 5).—The directions here given for the fumigation of nursery stock include plans for constructing a fumigating house and fumigating boxes.

White ants, W. W. FROGGATT (*Dept. Agr. N. S. Wales Farmers' Bul.* 60 (1913), pp. 46, pls. 4, figs. 9).—This account of termites deals with their general and Australasian distribution, structure of the nests, classification, injury, and preventive and control measures. A bibliography of papers dealing with the Australian white ants by 30 authors is appended.

Biology of the Thysanoptera, A. F. SHULL (*Amer. Nat.*, 48 (1914), No. 567, pp. 161-176).—This first part relates to the factors governing the local distribution of thrips.

Two new Thysanoptera from Porto Rico, J. D. HOOD (*Insecutor Inscitiæ Menstruus*, 1 (1913), No. 6, pp. 65-70, pl. 1).—*Heterothrips sericatus* from the flowers of guava (*Psidium guajava*) at Rio Piedras and *Podothrips semiflavus* from "para grass" (*Panicum barbinode*) at Guanica are described as new to science, the latter also representing a new genus.

On a collection of Thysanoptera from Porto Rico, J. D. HOOD (*Insecutor Inscitiæ Menstruus*, 1 (1913), No. 12, pp. 149-154, pl. 1).—Six species are here added to the known thysanopterous fauna of Porto Rico of which *Dinurothrips hookeri*, collected from *Ipomœa* sp. at Mayaguez, represents a new genus and species. It is pointed out that *Gynaikothrips uzeli*, a serious pest of the fig (*Ficus* spp.), appears to have been collected on tobacco in Porto Rico and may become of considerable economic importance.

Prosopothrips cognatus, a new North American thysanopteran, J. D. HOOD (*Canad. Ent.*, 46 (1914), No. 2, pp. 57-59, fig. 1).—*P. cognatus*, the species here described as new, was taken on wheat at Wellington, Kans.

The wheat louse (*Toxoptera graminum*), W. MOORE (*Agr. Jour. Union So. Africa*, 6 (1913), Nos. 3, pp. 482-492, figs. 12; 5, pp. 767-772; 6, pp. 973-977; 7 (1914), No. 1, pp. 50-60).—A general account of this pest, its occurrence in South Africa, natural enemies, and control measures.

A new American Phlebotomus, F. KNAB (*Insecutor Inscitiæ Menstruus*, 1 (1913), No. 11, pp. 135-137, fig. 1).—*P. atrocavatus* n. sp. is said to be of economic importance in Trinidad, where it occurs associated with man.

Preliminary characterization of the vector of verruga, *Phlebotomus verrucarum* n. sp., C. H. T. TOWNSEND (*Insecutor Inscitiæ Menstruus*, 1 (1913), No. 9, pp. 107-109, pl. 1).—The species here characterized for the first time has been found by the author to be the vector of verruga.

On the identity of verruga and Carrion's fever, C. H. T. TOWNSEND (*Science*, n. ser., 39 (1914), No. 994, pp. 99, 100).—This paper includes data relating to *Phlebotomus verrucarum* as an intermediate host of verruga infection.

Human case of verruga directly traceable to *Phlebotomus verrucarum*, C. H. T. TOWNSEND (*Ent. News*, 25 (1914), No. 1, p. 40).—The author reports upon the occurrence of this disease in his assistant in the verruga work, the cause of which he considers to be directly traceable to the bites of *P. verrucarum*.

Mosquitoes pollinating orchids, J. S. DEXTER (*Science*, n. ser., 37 (1913), No. 962, p. 867).—The author reports observations which indicate that the orchid *Habernaria obtusata* may be cross-fertilized by mosquitoes.

Further reports on flies as carriers of infection (*Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs.*, n. ser., No. 53 (1911), pp. 48, fig. 1).—Four papers are presented in this fourth report (*E. S. R.*, 25, p. 260), namely, An Experimental Investigation on the Range of Flight of Flies, by S. M. Copeman, F. M. Howlett, and G. Merriman (pp. 1-10); Memorandum on the Result of Examinations of Flies, etc., from Postwick Village and Refuse Deposit, with a Note on the Occurrence of the Lesser House Fly at Leeds, by E. E. Austen (pp. 11, 12); On the Part Played by Flies in the Dispersal of the Eggs of Parasitic Worms, by W. Nicoll (pp. 13-30); and Further Observations on the Ways in Which Artificially Infected Flies (*Musca domestica* and *Calliphora erythrocephala*) Carry and Distribute Pathogenic and Other Bacteria, by G. S. Graham-Smith (pp. 31-48).

The study of the rôle played by flies in the dispersal of the eggs of parasitic worms is summarized as follows: "Flies may convey eggs from excrement to

food and they may do so in two ways, namely, on the external surface of their body and in their intestine. The latter mode is practicable only in certain cases, where the eggs are of small size (under 0.05 mm. in diameter). On the external surface eggs of larger size (up to 0.09 mm. in the experiments) may be conveyed. Eggs adhering to the external surface are usually got rid of by the fly within a short time, but those which are taken into the intestine may remain there for two days or longer. The eggs which are conveyed in either of these ways may remain alive and subsequently cause infection. There are only certain parasitic worms in the dissemination of the eggs of which flies are likely to play an important part. This is determined in the individual cases by the nature of the parasite's life history and the resisting powers of its eggs. Material containing eggs of parasites and in particular ripe segments of tape-worms may remain a source of infection through flies for as long as two weeks.

"The eggs of the following parasitic worms have been shown experimentally to be capable of being carried by *M. domestica*: *Tania solium*, *T. serrata*, *T. marginata*, *Hymenolepis nana*, *Dipylidium caninum*, *Dibothriocephalus latus* (?), *Oxyuris vermicularis*, *Trichuris* (*Trichocephalus*) *trichiurus*, both internally and externally; *Necator americanus*, *Ankylostoma caninum*, *Sclerostomum equinum*, *Ascaris megalocephala*, *Toxascaris limbata* (= *Ascaris canis* e. p.), *H. diminuta* externally only. No trematode parasites have as yet been experimented with.

The observations of Stiles that the larval fly can ingest ascarid eggs and pass them on to the adult fly lacks confirmation."

The peach tree borer (*Sanninoidea exitiosa*), E. N. CORY (*Maryland Sta. Bul.* 176 (1913), pp. 181-218, figs. 14).—This bulletin presents details of investigations of the life history of the peach tree borer and of control measures therefor based upon a period of 4 years' observations. In conducting the life history work 3 special cages inclosing 2-year-old nursery trees free from borers and eggs were made use of.

The greatest number of eggs deposited by a single moth was 161. Of all eggs deposited 390 were placed on the leaves and 65 on the trunk. The shortest period of incubation was 10 days, the longest 16½ days (in September), and the average 13 days. The earliest record of pupation was that of a larva collected May 31, 1910, which pupated on June 1. The pupal stage averaged 22 to 23 days in duration during the height of the season. "Of those that pupated June 1, 1910, the first male appeared on July 3, the first female July 7. Larvæ that pupated June 16, 1910, produced both males and females on July 11, 1910, a period of 25 days. In one case an infested tree trunk was brought into the laboratory in late fall, 1908, from which a male moth issued on December 9, 1909."

The natural enemies observed include *Telenomus quaintancei*, reared from eggs deposited on August 21, 1911; and *Bracon* sp. and *Macrodyctium* sp., reared from pupæ. An undetermined fungus parasite is said to increase largely the mortality of the pupæ.

The control measures have been summarized by the author under the headings of cultural treatments and mechanical barriers and repellents as follows: "Tobacco dust and earth mounds gave immunity for the first year, but on trial the second year failed to keep out the worms. Carbolic fertilizer and earth mounds gave poor results in one year's trial, so was not continued. Apterite and earth mounds did not give good results in that the material not only did not keep out the borers, but it also caused the formation of collar galls.

"Tanglefoot has never proved of value in any tests we have made and has always injured the bark to a considerable extent, the injury depending upon the age of the tree. Theoretically, it is an ideal barrier. Tanglefoot and

arsenate of lead is more injurious to the bark than tanglefoot alone. Gas tar has been highly recommended by various workers, but has never proved successful in our work and has injured the trees to some extent. We could not recommend its use on young trees. Pyroligneous acid, in addition to proving ineffective in keeping out borers, will very likely prove too expensive for large plantings. Rubberoid roofing paper, sheathing paper, and newspapers have not proved effective barriers, primarily because of the difficulty in making the union between the wrapping and the tree tight enough to prevent the entrance of the larvæ. Should the above purpose be effected the probable outcome would be that the larvæ would enter above the wrapping. The work of attaching protectors of any kind is a considerable item of expense. Wire protectors rust out quickly, are expensive, and do not protect. Wood veneer cracks and warps and a tight union is an impossibility; it is ineffective in keeping out borers. White lead and linseed oil has injured the bark on some of our trees and can not be depended on to prevent the entrance of the larvæ. White lead, linseed oil, and arsenate of lead is unsatisfactory, as it injures the bark to an appreciable extent. It does not prevent the entrance of borers. White lead, linseed oil, and lead chromate presents the same difficulties as the foregoing. All paint mixtures caused a blackening of the outer bark and gummosis, in addition to the fact that they were ineffective in keeping out borers. Concentrated lime-sulphur (commercial brand) has been highly recommended at various times, but in the author's experience with it on young trees it has not proved effective in keeping out the borers. The practice of spraying the crowns after the 'worming' to prevent fungus trouble is a good one." The addition of arsenate of lead to concentrated lime-sulphur apparently does not add to the effectiveness of the material. Atomic sulphur and arsenite of zinc and Hale's wash killed the trees on which they were applied and are strongly condemned. Quaintance wash, made from glue, builder's hair, and lime, was proved ineffective and undesirable from a laborer's standpoint. Arsenate of lead scaled off too quickly to be effective. Fish-oil soap rosin is not lasting enough nor is it effective for even a short period. Fish-oil soap and arsenate of lead besides being too easily washed off caused gummosis, probably due to the arsenical.

An annotated bibliography of 14 pages arranged chronologically is appended.

The sandwich caterpillar (*Agriophara rhombota*) (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, 1912, No. 1, pp. 2-5).—This caterpillar is said to occur commonly throughout the tea districts of northeastern India, occasionally becoming a serious pest.

The cabbage webworm, a pest of cabbage and allied plants, R. W. JACK (*Rhodesia Agr. Jour.*, 11 (1914), No. 3, pp. 416-422, pl. 1).—This Rhodesian pest is thought to be same as our imported cabbage webworm (*Hellula undalis*).

Leaf miners of the Hawaiian Islands, O. H. SWEZEY (*Proc. Hawaii. Ent. Soc.*, 2 (1913), No. 5, pp. 221-227).—Of the leaf miners here treated 21 belong to the Lepidoptera, 4 to Diptera, and 2 to Coleoptera.

The coconut beetles, *Oryctes rhinoceros* and *Rhynchophorus ferrugineus*, I. H. BURKILL (*Gard. Bul. Straits Settlements*, 1 (1913), No. 6, pp. 176-188).—This paper discusses the present status of these pests and control work in the Straits Settlements.

Bark beetles (Ipidæ) which injure useful tropical plants, M. HAGEDORN (*Tropenpflanzer*, 17 (1913), Nos. 1, pp. 43-51; 2, pp. 99-104; 3, pp. 154-160; 4, pp. 211-216; 5, pp. 266-270, figs. 19).—This paper deals with 42 bark beetle enemies of 19 different useful plants, including 1 species which attacks cotton, 7 species which attack coffee, 8 species which attack cacao, 11 species which attack various species of rubber trees, 2 species which attack sugar cane, etc.

Bee keeping for farmers, R. G. WARRY (*Dept. Agr. N. S. Wales Farmers' Bul.* 76 (1913), pp. 19, figs. 2).—A popular account.

Type species of the genera of ichneumon flies, H. L. VIERECK (*U. S. Nat. Mus. Bul.* 83 (1914), pp. 186).—This bulletin is the result of an attempt to put each ichneumonoid genus, of which there are more than 2,000 with some 25,000 species, upon a definite basis.

Descriptions of new Hymenoptera, VI, J. C. CRAWFORD (*Proc. U. S. Nat. Mus.*, 45 (1913), pp. 241-260, figs. 2).—Several of the species here described as new are of economic importance as parasites of insect pests. Among them mention should be made of *Ganaspis hookeri*, which was reared from the mango fruit fly at Mayaguez, P. R.; *Coccidoxenus portoricensis*, reared from the wax scale, at San Juan, P. R.; *Sympiesis metacomet* and *S. massussoit*, reared from swamp white oak leaves infested with *Lithocolletes hamadryella*, at Auburn-dale, Mass.; and *Anagrus giraulti*, reared from *Phthorimæa operculella*, at El Monte, Cal.

Descriptions of new Hymenoptera, VII, J. C. CRAWFORD (*Proc. U. S. Nat. Mus.*, 45 (1913), pp. 309-317, fig. 1).—Most of the species here described are of economic importance, among them *Polycystus foersteri*, *Derostenus agromyza*, *D. arizonensis*, *D. variipes*, *Entedon thomsoni*, *Pleurotropis utahensis*, and *Cirrospilus flavoviridis*, which are parasitic upon species of flies of the genus *Agromyza*.

A new species of mealy bug parasite (*Aphycus terryi*), D. T. FULLAWAY (*Proc. Hawaii. Ent. Soc.*, 2 (1913), No. 5, p. 281).—This parasite was reared from *Pseudococcus saccharifolia* at 2 localities on the island of Maui and at Hilo, Hawaii.

Parasites of the San José scale, H. T. FERNALD (*Ent. News*, 25 (1914), No. 1, p. 39).—It is stated that during the fall of 1913 from 75 to 85 per cent of the San José scale in orchards at Amherst, Mass., appeared to be parasitized by *Prospaltella perniciosi*, and that as large a percentage occurred on the small twigs as on the large ones. The evidence at hand is said to indicate that this species is the most active parasite of the San José scale in Pennsylvania. See also previous notes (*E. S. R.*, 29, p. 758).

Careful examination of twigs from Pennsylvania and Massachusetts indicates that in spite of the high percentage of parasitism it is hardly to be expected that the scale will become an unimportant pest while as high as 10 per cent of the scales are left to reproduce.

Pteromalids (Pteromalidæ) parasitic upon Hessian fly (*Mayetiola destructor*) with descriptions of two new species, N. V. KURDJUMOV (*Reprint from Ent. Věstnik [Kiev]*, 2 (1913), No. 1, pp. 4, figs. 5; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 2, pp. 65, 66).—A description in English is given of *Eupteromalus arvensis* n. sp., a common parasite of *Mayetiola destructor* in Poltava, Moscow, and Kiev, and *Meraporus crassicornis* n. sp., reared from the Hessian fly's cocoon at Poltava and in Kiev.

Notes on Pteromalidæ (Hymenoptera, Chalcidoidea), N. KURDJUMOV (*Russ. Ent. Obozr.*, 13 (1913), No. 1, pp. 1-24, figs. 2).—This paper includes a synopsis of the genera of the subfamily Pteromalinæ.

FOODS—HUMAN NUTRITION.

Wheat investigations, E. F. LADD (*North Dakota Sta. Rpt.* 1912, pt. 3, pp. 295-347, figs. 11).—Brief statements are made regarding the wheat investigations carried on in the 5 years which have passed since the experimental mill was installed at the station. These are followed by a number of articles on wheat and milling by T. Sanderson and W. L. Stockham.

Durum wheat of the 1911 crop (pp. 298-305).—The results of milling and baking tests reported in this comparison of durum wheat of the crop of 1911 with the same variety grown in previous years and with hard red winter wheats of the crop of 1911 led to the conclusion that the 1911 durum wheat "was superior in practically all tests of quality to that of any of the preceding years since the beginning of our tests. Considering the products to be of equal value it would yield as large, if not larger, commercial returns to the miller and baker than any other type of hard wheat tested during the year."

It was also "superior to hard red spring wheat, grown upon the same farms, in grade, flour yield, texture, water absorption, and protein content. The hard red spring wheat excelled in color and baking strength.

"Durum wheat requires more care in baking than hard red spring, as it does not absorb the necessary water as readily. It has a shorter fermentation period. The durum bread is more yellow in color.

"The patent flour of durum wheat is superior to the hard red winter straight when considering 1911 samples. Winter wheat is decidedly lower in protein content and water absorption of flour than the durum."

The influence of the amount of rainfall on the yield and quality of wheat (pp. 305-324).—Data are given regarding the amount of rainfall together with the results of studies of the grade, chemical composition, and milling and baking qualities of wheat crops of 1911 in comparison with earlier years. The authors point out that wide variations in the rainfall in North Dakota are noted.

"The yield of wheat per acre is greatest in regions with a good rainfall and very low where the rainfall is slight. Wheat grown in the dry sections ranks higher in grade. Wheat grown in the dry sections produces a slightly higher percentage of flour. Wheat grown in wet regions yields flour of greater baking strength but varying more from sample to sample. Wheat from the dry region yields flour of slightly better color on the average. The lower grades of wheat, which are shrunken, rank high in protein content. Wheat from dry regions has a higher protein content than that of the same grade from a region of higher rainfall."

Strains of Fife and Bluestem wheats (pp. 324-328).—Data are brought together regarding a number of samples of Fife and Bluestem wheats grown in different years. The figures, according to the authors, do not indicate any important difference between these two sorts of wheat or between the strains, though, judging by the available figures, "it appears that Bluestem is somewhat more subject to variation in quality."

The relation of the amount of moisture in the soil at the time of maturity and the protein content of hard red spring wheat (pp. 329-331).—As a part of this study the moisture content of the soil was determined. A number of samples of wheat were compared and the range in water content was found to be from 4.60 to 33.22 per cent and in protein content from 9.14 to 18.72 per cent. From the data regarding moisture the conclusion was reached that "it takes considerable change in moisture content of the soil . . . to make much of a change in the protein content of the wheat."

Hard red spring wheats scoring low in color and texture (pp. 332-336).—The authors note that in milling the same wheat at different times variations in the color and texture score of the product were noted which were attributed to differences in climate, in tempering, and in milling. Scores for a number of samples low in color were brought together and compared to see whether more definite information could be gathered. According to their conclusion, the data presented were not sufficient to determine the effect of the various inseparable

impurities or the effect of any one kind of damage, such as frost or bin burning, but were sufficient to show that their combined influence was very marked.

Hard red spring wheat containing a high percentage of moisture (pp. 337-339).—To judge the effect of a high water content, samples of wheat containing above 13.5 per cent of water were compared with the general average of samples for the same years. "The effect of moisture on the weight per bushel is approximately the same for each of the 4 years and much as one would expect. Water is lighter than chaff wheat. It swells the wheat and thus reduces the test weight. The relation of the protein is not so definite. . . . The yield of flour from the wet wheats is approximately as much below the average for the various years as the moisture content is above, with the exception of the year 1911. . . . The wet samples lose more in milling than the average, which is in accord with results previously obtained. Most of the rejected wheats have fallen into this high moisture class, thus indicating the danger of storing wheats high in moisture. The color and texture of the high moisture wheat would rank above the average were it not for the presence of these rejected samples."

Moisture in the soil early in the spring and the dockage of hard red spring wheat (pp. 340-342).—The data brought together in the tables, according to the authors, do not confirm the popular opinion that wet springs, which mean vigorous growth of wheats, are responsible for high percentages of weed seeds in the wheat crop. However, "it may be that some of the samples were partially cleaned before arriving at the mill or that the nature of the preceding crop or time of plowing were more important factors in weed development."

Protein content of hard red spring and durum wheats from the same farm (p. 343).—The data reported for 5 samples of hard spring, durum, and winter wheats grown on adjacent fields in 5 counties showed an average protein content of 16.55, 17.48, and 15.28 per cent, respectively.

Variation in loss in milling (pp. 343-347).—Data are brought together regarding the loss in milling noted in wheats in the years 1908 to 1911, inclusive. According to the authors, "there is considerable variation in the loss in milling within the month and from month to month. The loss is greater in the winter time, on the average, than during the other months. This is significant, inasmuch as the precipitation is lightest at that portion of the year. Most mills are probably drier during the winter, because of artificial heat. The wheat in the elevator takes more moisture because of the humid condition during the winter and has more to lose."

Wheat study and investigation from a milling and baking standpoint, E. F. LADD (*North Dakota Sta. Rpt. 1912, pt. 3, pp. 348-396, fig. 1*).—The work of the station on the grading of wheat with reference to its bread making quality is reviewed, and tabular data showing milling and baking tests are reported and discussed.

According to the report, the data at hand do not cover a long enough period to permit the drawing of conclusions regarding all of the many factors given. A study of the more prominent tables shown "would indicate that the method now employed in the grading of wheat does not give proper value to the lower grades of wheat—that is, Nos. 2° and 3°—at least. The number of samples that we have had in the No. 4° and rejected grades were too small to allow . . . any very fair comparison to be made; but the comparison can be made down to No. 3° fairly well. The factors that stand out the clearest in favor of the lower grades are the percentage of flour obtained from them, the amount of water the flour will absorb, the volume and color of the loaf produced."

The data summarized also show that the method of grading is not satisfactory when compared with the prices paid for the wheat and those received for the mill products obtained from it.

A study of the effect of mean temperature during the growing season on the quality and grade of wheat, E. F. LADD (*North Dakota Sta. Rpt. 1912, pt. 3, pp. 404-431, figs. 4*).—Analyses and milling and baking tests are reported for wheats grown at mean temperatures ranging from a little below 60° to a little above 66° F.

The recorded tabular data show "that the mean temperature of the entire growing season is not an important factor; while there is no doubt that the temperature from day to day does have its effect. The mean temperature does not have any marked effect further than to show that the wheat produced with a mean temperature of above 60° and below 66° F. seems to produce a flour of a better baking quality than that produced below 60° and above 66°. The number of samples we have had to work with along this line have been limited; in many cases only having received one sample. In such cases it is not fair to draw definite conclusions."

Foreign types of wheat, crops of 1908-1910 and 1911, E. F. LADD (*North Dakota Sta. Rpt. 1912, pt. 3, pp. 396-403*).—The results are reported of milling and baking tests with a number of different types of foreign wheats. General deductions were not drawn.

Eighteenth report on food products, and sixth report on drug products, 1913, J. P. STREET (*Connecticut State Sta. Rpt. 1913, pt. 4, pp. 257-308*).—During the year 1913 the total number of samples examined was 1,902, of which 1,055 were not found adulterated, while 530 were adulterated or below standard and 68 compound.

Analytical and other data are reported regarding the character and composition of breads baked in Connecticut; candies, mostly of the cheaper sorts; "dehydro foods" (evaporated or concentrated vegetables and fruits), "prepared chiefly for travelers or campers who wish to carry food in a concentrated form"; diabetic foods; ice cream powders; jelly powders; canned pumpkin; some cereal breakfast foods; a pudding compound; powdered milk; coffee substitutes; "health biscuits," and cheese. Data are also given regarding the examination of dairy products and miscellaneous food samples, as well as the results of the examination of drug products and Babcock test glassware.

The cost of the samples of bread examined is discussed, among other matters. "The bread cost from 4.2 to 6.9 cts. per lb., with an average of 5.7 cts. The average cost per lb. in the 3-ct. loaf was 3.9 cts., in the 4-ct., 4.8 cts., in the 5-ct., 5.8 cts., in the 8-ct., 5.4 cts., and in the 10-ct., 5.8 cts. The cheapness of the 3- and 4-ct. loaves indicated, therefore, a real saving, as far as quantity is concerned, because the relative decrease in price was greater than the decrease in weight. The data for the 8-ct. loaves are limited to 3 samples, but these indicate that this sized loaf is a cheaper purchase than the 5-ct. loaf, about double the weight of bread being furnished for an increase in price of but 60 per cent."

From the actual weight of the samples of bread in comparison with the claimed weight, the author concludes that there is no special difficulty in maintaining the weight claimed.

In the case of the candies examined, "no foreign fat was found in any of the chocolate coatings, and no added mineral matter except in 1 sample of molasses kisses, which contained 3.78 per cent of ash.

"All but 2 of the 25 marshmallows contained gelatin. In many of these the adhering powder, consisting of powdered sugar and starch, was excessive, in 2 cases amounting to 2 oz. in the pound. . . .

"All but 2 of the 11 samples of licorice lozenges contained charcoal, in 1 case 0.23 per cent.

"None of the 4 samples of coated peanuts contained arsenic in the coatings."

Coal tar dyes were found in a number of the samples, some of them unpermitted colors.

Short weight was noted with 35 out of the 189 samples of candies examined.

Foods, drugs, and sanitation, E. F. LADD ET AL. (*North Dakota Sta. Rpt. 1912, pt. 2, pp. 288, figs. 2*).—This report covers work carried on up to November 1 in the calendar year 1912. Many pure food and drug topics and related matters are discussed, data presented regarding the examination of miscellaneous foodstuffs and drug products and regarding the sanitary inspection of groceries, restaurants, and so on, a number of formulas given for preserving fruits for display. Some experimental work is also reported.

It is pointed out that since the state law has been in operation marked improvement in conditions has been noted, approximately 95 per cent of the foods reported by the inspectors in 1912 being found to conform with the legal requirements. A similar improvement has been noted as a result of the sanitary inspection of places where foods are prepared, handled, stored, and disposed of.

The dangers from exposing foods to dust are discussed and the results of a test are given showing that grapes exposed in a basket upon the sidewalk in front of a store had 3,000,000 bacteria per grape on the outside of the cluster as compared with 780,000 on the inside. "The grapes from the outside of the cluster were found to contain colon bacilli, approximately, 5 per cc. of the washing water, or 100 colon bacilli per grape. The presence of intestinal bacilli gathered from the street dust shows the danger to which one is subjected when eating fruit of this kind, as is a common practice especially among younger children."

The results of a study of mince-meat and mince-pie filling are reported, and give information as to the composition and character of such goods. It is noted that at least a part of the manufacturers and dealers "are endeavoring to comply with the law, and are using a full 10 per cent of clean, wholesome meat in their different brands of mince-meat."

In connection with the examination of milk and other dairy products, the results of 8 analyses of human milk are presented.

The data gathered in a preliminary study of the effect of preservatives upon ciders seem to indicate that different apple juices act dissimilarly under the influence of sodium benzoate. "Doubtless an ultimate analysis of each experimental sample at stated intervals would assist in solving the problem."

A preliminary study was made of sorghum sirups, and ash analyses and other analytical data are reported. Definite conclusions can not be drawn, it is stated, until more work is done on the ash content. This factor appears to be rather constant in pure sorghum sirups. "This ash content of molasses and other sirups should be studied, as a clue to the grade and class of these products might be obtained . . . [from the composition of the ash]." It is stated that work of this character will be continued.

A report on rice, which is included, takes into account the facing of rice and summarizes data of other investigators as well as information regarding the protein and ash content of rice and its value and uses as food. Data regarding ash constituents and methods of detecting the facing of rice are given, and a study of rice oil was made, a number of samples being examined, particularly with reference to the detection of various oils "used sometimes to make rice appear a better quality; also to improve the appearance of good grades of rice and give them a finish."

An extended study of tomatoes, with special reference to canned tomatoes, is also included in the report, which summarizes data regarding the composition

of tomatoes as influenced by variety and other conditions, discusses the problems of tomato canning, and gives analyses of a large number of fresh tomatoes, canned tomatoes, and other tomato products, together with a bibliography of tomato literature.

In a study of the acid constituents of tomato juice "the acids of fresh tomato juice and canned tomato juice were found to be oxalic and citric, with perhaps a very small amount of malic acids. The greatest amount of the acid in tomatoes is due to oxalic acid."

[Food analyses and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 2 (1913), No. 20, pp. 341-350, figs. 3).—A number of pure food and drug topics are discussed, and information is given regarding the examination of miscellaneous foods, a proprietary remedy, and a number of samples of ferric chlorid.

A study of The Crease of the Wheat Kernel, by W. L. Stockham, which included data obtained with a number of samples, led to the conclusion "that the closed type of kernel produces a somewhat superior product on the average than does that with an open crease. Better results could probably be obtained if each sample had all its kernels of the type it represented. Because of present variation in type of crease, its relation to seed treatment, and milling quality, the crease offers as many if not more possibilities as a basis for selection than many factors now employed."

[Food analyses and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 2 (1913), No. 21, pp. 357-368).—Some data are given regarding the relative cost of a meal in hotels and restaurants of different grade and the relation of fancy marketing of food products to the cost of living. Pure food and drug topics are discussed and information given regarding the examination of miscellaneous foods, beverages, etc.

A sample of cloth said to have been purchased as "all wool" flannel was examined and found to contain approximately $\frac{2}{3}$ cotton and $\frac{1}{3}$ wool. "This is characteristic of a good share of the material sold as 'all wool' or 'commercial wool.'" The need for a textile law is urged.

[Food analyses and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 2 (1913), No. 22, pp. 373-392, figs. 2).—Miscellaneous food and drug topics are discussed and data reported regarding the examination of proprietary remedies, miscellaneous foods and beverages, and a number of samples of canned celery and tomato soups.

"The several constituents in these soups vary greatly, as for example, in the celery soups the percentage of sugar varies approximately from 0.08 to 1.37 per cent; while the total solids or extract for the same soups ranges from 3.08 to 8.49 per cent and in the tomato soups the range is even greater, or from 1.57 to 11.65 per cent."

It is stated that a number of samples of bottled carbonated beverages, "pops," have been submitted for examination, because either the bottle or its contents showed an insanitary condition. As yet experiments have not been made with such goods at the station, but the belief is expressed that manufacturers have sometimes been careless with respect to cleanliness and sanitary conditions, and attention is directed to the fact that illness may be conveyed by this means, particularly when the "pop" is drunk from the bottle, as is often done by children.

T. Sanderson reports a study of Milling and Baking Results of Marquis Versus Bluestem and Fife Wheats which takes into account the quality of the wheat as well as the results of milling and baking tests. Some variations were noted.

but, in general, milling results were in favor of the Bluestem and Fife wheats, while Marquis wheat had a slight advantage as shown by the baking tests. From the results obtained the author is of the opinion that there can be no harm in the continued production of Marquis wheat, and recommends that home-grown seed should be used as far as possible. "If this wheat will continue its present quality, there can be very little objection raised from a milling and baking standpoint to its production in large quantities."

A paper by W. L. Stockham is also reported, on Marquis Wheat—Protein Content, Strength, and Adaptability. As shown by the analyses reported, Marquis wheat flour had a lower protein content than spring wheat flour, while there was on an average little difference in the moisture content of the flour. As shown by baking tests, the bread made from Marquis wheat flour ranked in color a little lower than that from the other hard red wheats grown the same year, though the general average was good. From the data reported and discussed the author concludes that although "Marquis may be widely grown it will not maintain its standard in all sections of the State."

[Food analyses and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 3 (1914), No. 1, pp. 1-8, 12-32).—Baking powder frauds and other pure food and drugs topics are discussed and some information is given regarding some proprietary remedies.

A report is presented by T. Sanderson, entitled *A Study of the Variation in Weight of a Fifty-Pound Sack of Flour during Storage*. The flours used were blends of hard red winter wheats and hard red spring wheats, some of the latter samples graded down or "rejected" on account of having been sprouted or sprouted and bleached. The different flours, in 50-lb. sacks, were stored in the usual way from a little under 7 months to 11 months, weighings being made at intervals. Small gains and losses were noted with different flours, but, considering the 38 samples as a whole, there was an average gain of 0.2077 per cent in weight; or, leaving out of account 4 samples which were dried out, the average gain was 0.3257 per cent.

"The variation in weight is due largely to atmospheric conditions . . . during the spring and early summer moisture was lacking and ran below normal and during that period . . . the greatest losses in weight were experienced. Then during the latter part of June and July when the rains came all samples show material gains. . . . Temperature and condition of storeroom and atmospheric conditions should be considered when enforcing the food law. . . .

"Flour is more susceptible to variations in the summer months than in the winter.

"Wheat milled with a high moisture content is more liable to produce a flour that will lose in weight in storage than a wheat of low moisture content. . . .

"Moisture added in the tempering of wheat is, in this climate, very largely lost again in the storage of flour."

The baking quality of the flours was also taken account of. "The difference in the baking quality of the flour from both the hard red spring and the hard red winter wheat on standing, is very slight. In the case of the hard red spring, the color and texture show the only mentionable difference, while the hard red winter shows a slight gain in absorption, volume, and color."

With the other flours the difference in the average baking quality between the first and second baking was practically nothing, the individual samples varying a little in each case.

A study was also made of the gains or losses in weight during storage and the effect of storage on baking quality of hard red spring wheats blended with

from 3 to 15 per cent of barley and with from 3 to 15 per cent of rye, the bread being compared with bread made from barley and from rye alone. The samples containing from 3 to 15 per cent of barley all showed a loss, while those containing from 10 to 15 per cent barley and all samples containing rye showed widely varying gains in weight. No explanation of these variations is suggested, though the author does not believe that the barley or the rye had anything to do with it, as the amount of moisture added by these grains to the total originally present was very small. The baking test did not show "any material difference in either case, except in the color of the last baking of the rye blend which is noticeable owing to the low color score received by the 5 per cent rye mixture."

[Food analyses and other pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 3 (1914), No. 2, pp. 16, figs. 5).—Sugar vinegar is briefly discussed and other food and drug data presented.

In studies of wheat, which are reported, Velvet Chaff is compared with Fife and Bluestem. The different types of hard red spring wheats grown in North Dakota were considered from the milling and baking point of view, on the basis of data furnished by T. Sanderson, and the rank of Velvet Chaff among other spring wheat varieties in baking strength and protein content, in 1913, on the basis of material furnished by W. L. Stockham.

The conclusions drawn from the work were substantially as follows:

It has not been shown that the disparity in price between Minneapolis and Chicago markets for wheat is to be attributed to Velvet Chaff, but to the law of supply and demand.

Velvet Chaff appears in the past to have been used for mixing to raise the grade of other wheats and this to the disadvantage of the farmer. This wheat, lying between Fife and Bluestem in shape, is admirably adapted for mixing purposes, and in a mixture is hard to identify with any great degree of accuracy.

It would appear from the milling and baking records reported that some of the evils in flour attributed to Velvet Chaff, owing to seasonal conditions, are in reality chargeable to other standard varieties of wheat, namely, Fife and Bluestem. In general Velvet Chaff wheat of average quality ranks well with Bluestem one year with another, and in some seasons has averaged better than Bluestem. The authors are of the opinion that if all the Velvet Chaff wheat were to be uniformly blended with hard spring wheats, Fife and Bluestem, the quality of the bread could at the most be but slightly affected.

"Velvet Chaff has always stood above hard red winter wheat, considerable quantities of which are reported to be used in Minneapolis mills, especially when there is a shortage of hard red spring wheats.

"An examination of all the data shows that the variation in Fife and Bluestem wheats is just as great as that for Velvet Chaff wheat, and individual samples have been shown to be inferior to Velvet Chaff."

It has not been proved that Marquis wheat is well adapted to all parts of North Dakota, and there is evidence to indicate that for the drier part of the State it may not be well adapted.

"The effort being put forth to induce the farmers to take up the growing of Marquis wheat can only be justified when it is found that Marquis wheat does well in all parts of the State and produces a good milling and bread-producing flour."

Report of the work of the bakery laboratory, MOHS (*Ztschr. Gesam. Getreidew.*, 5 (1913), No. 9, pp. 258-261).—This report, which covers the first half of the current year, gives information regarding the samples of various

flours examined, the bread yield of different sorts of flour, malt preparations, a substitute for solid fat, yeast, dried milk preparations, equipment, and similar topics.

The composition of various milks and their adaptability for infant feeding, F. AGCAOLI (*Philippine Jour. Sci., Sect. A*, 8 (1913), No. 3, pp. 141-150, pt. 1).—A comparative analytical study of milks used for infant feeding in the Philippines, including human, carabao's, goat's, cow's milk, Australian cream, and various brands of sterilized, condensed, and dried milk. Directions for modifying milk are given.

The biological significance of phosphorus to the growing organism.—II, Analyses of organs with respect to the content of phosphorus and intracellular ferments, M. MASSLOW (*Biochem. Ztschr.*, 56 (1913), No. 3, pp. 174-194).—Continuing the report of previously described experiments with laboratory animals (dogs) fed on diets varying as to the amount and character of phosphorus provided (E. S. R., 30, p. 465), the author gives in detail the amounts of total inorganic and organic phosphorus and of phosphates found in the organs of the different animals and also the amounts and functional energy of catalase, lipase, amylase, and diastase in brain, liver, kidneys, heart, and lungs.

From the results he concludes that the addition of inorganic phosphorus to a diet lacking in organic phosphorus is of no service to the organism, which first draws upon its reserves of phosphorus and then shows a decline similar to that of phosphorus starvation. Inorganic phosphorus and glycerophosphates appear to be resorbed but not to be capable of taking part in the formation of complicated combinations in the body cells. Similarly the amount and functional energy of the intracellular ferments appear to be adversely affected by a lack of organic phosphorus in the diet.

Respiration and cell energy, H. A. WAGER (*Trans. Roy. Soc. So. Africa*, 2 (1912), pt. 5, pp. 405-418; *abs. in Bot. Centbl.*, 123 (1913), No. 4, p. 86).—Respiration, the author points out, "is not a function of any particular organ of a body but is a process going on in each individual cell. Thus, the lungs should not be called the organs of respiration—they are only accessory organs. The kidneys might just as well be considered as further organs of respiration in so far as they remove the decomposition products indirectly from the respiring cells, and the heart in so far as it pumps the respiring medium through the body."

From the digest of data presented, dealing chiefly with reference to vegetable life, the following conclusions were drawn:

"The energy required in the metabolism of colorless cells is not obtained from the sun either directly or indirectly. The protoplasm in colorless cells only uses energy set free by some chemical union taking place either in the cell or by the introduction of external elements into the cell. In no case is energy obtained by the decomposition of substances in the cell, as indeed energy is required to bring about such decomposition. Energy is not required for synthesis of compounds for which chemical affinity is responsible, although undoubtedly chemical affinity is inextricably connected with energy. No plant substance contains a store of directly available energy. Respiration is not a process apart from nutrition. The term respiration should be used exclusively to mean the interchange of gases taking place in each individual cell. . . . Water is the respiratory medium of a large number of the living cells in trees."

A formula for the determination of the surface area of infants, J. HOWLAND and R. T. DANA (*Amer. Jour. Diseases Children*, 6 (1913), No. 1, pp. 33-37; *abs. in Zentbl. Biochem. u. Biophys.*, 15 (1913), No. 12-13, p. 484).—A formula is given which is a modification of one used for adults.

ANIMAL PRODUCTION.

The domestication of animals, W. F. PYCRAFT (*Sci. Amer. Sup.*, 77 (1914), No. 1984, p. 21, figs. 2).—The author points out that the number of animals which man has succeeded in bringing into subjection does not exceed 26, and to make up this number animals like the elephant, llama, camel, yak, and reindeer must be included. Thus far attempts to domesticate the eland and zebra have proved unavailing, but it is now thought that by hybridizing these intractable creatures with domesticated animals some progress in domestication can be made. Examples of this are the crossing of the bison and the zebu with common cattle, the aim being greater size, stamina, and immunity to disease.

The production of such animals as the blue fox, skunk, mink, and sable for commercial purposes has come into common practice and marks a step in the utilization of these animals.

Isolation and selection allied in principle, J. T. GULICK (*Amer. Nat.*, 48 (1914), No. 565, pp. 63, 64).—In this article the author shows wherein isolation and selection are alike in transforming the hereditary characters of a species, and contends that "in the case of a variable and plastic organism, races more or less divergent will be produced, if for many generations the organism is divided into branches that are prevented from crossing."

Fermentation process in the digestion of ruminants and swine, J. MARKOFF (*Biochem. Ztschr.*, 57 (1913), No. 1-2, pp. 1-69, figs. 2).—A comparative study of the content of carbon dioxide, methane, hydrogen, organic acids, and other fermentation products of the stomach and intestines of cattle and swine under various feeding conditions. There is included a description of the apparatus used in collecting and determining the amount of these products.

Retention of maltase in the blood serum of hungry and fed animals, T. KUMAGAI (*Biochem. Ztschr.*, 57 (1913), No. 5-6, pp. 375-379, figs. 6).—The results of experiments with dogs indicated that the loss of maltase in the blood serum of hungry animals was greater than in that of fed animals. This bears out the results of former studies made on sheep, calves, and swine.

Ensilage and the production of milk and beef during the winter months, D. H. DE BURGH (*Dublin and London*, 1913, pp. 53, pls. 19).—In this booklet the author treats of the Irish method of ensiling grasses, hays, and fodder crops. Of especial interest is the description of methods of making sweet silage. It is stated that practically all the leading crops grown in the British Isles are suitable for making silage. The stronger grasses, such as cocksfoot, foxtail, timothy, dogstail, come out in fine condition, and wild vetch comes out well. Yellow shamrock clover comes out perfectly green while trefoil comes out brown, but sound. Most weeds, such as thistles and docks, come out well, while ribleaf always blackens.

The author emphasizes the importance of proper temperature in making silage. This temperature is set at about 122° F. and the silage crop is put into the silo only as this temperature is reached by the material already ensiled. To prevent overheating the material is watered after being placed in the silo.

Silo facts from Missouri farmers, J. K. WRIGHT (*Missouri Bd. Agr. Mo. Bul.*, 11 (1913), No. 9, pp. 108, figs. 12).—This is a bulletin in popular style, largely compiled from answers received in reply to inquiries submitted to about 1,000 farmers in the State. The subjects discussed include silage crops, cost of silage, filling the silo, preventing the spoiling of silage on top, the feeding of silage, supplements to use with silage, cost of harvesting and value of silage, and silo construction. Summarized accounts of station experiments in the feeding of silage to all classes of farm stock are also given.

The present state of the potato-drying industry in Germany, E. PAROW (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 9, pp. 1342-1345).—The total consumption of potatoes in Germany is estimated at 40,000,000 tons, of which 16,000,000 tons goes for cattle feed. Production is exceeding consumption with an attending waste, but potato drying is reducing the annual loss. The number of factories has increased $3\frac{1}{2}$ times in the past 5 years. One and one-half million tons of potatoes make 400,000 tons of the dried material. The technical development of potato drying has reached a high degree of perfection. In this article a number of standard processes are described.

Numerous feeding experiments have shown both slices and flakes to be sound concentrated feeds, relished by all classes of stock.

[Feeding stuff analyses] (*Fla. Quart. Bul. Agr. Dept.* 23 (1913), No. 3, pp. 210-219).—Analyses are reported of molasses feeds, wheat shorts, wheat midlings, cotton-seed meal, linseed meal, alfalfa and mixed feeds, and various proprietary feeds.

Stock feeds, J. W. INCE (*North Dakota Sta. Rpt.* 1912, pt. 3, pp. 432-434, 436).—Analyses are reported of cotton-seed meal, wheat screenings, prairie hay, pigeon grass, and various mixed and proprietary feeds.

Length of neck of lowland and highland cattle, G. LAUREE (*Deut. Landw. Tierzucht*, 17 (1913), No. 50, pp. 593, 594).—Measurements were made of the necks of various types of lowland and highland cattle, and the ratio between the length of neck and width of rump and height at the withers determined. It was found that the necks of the lowland cattle were the longer, but not so well muscled as those of the highland types.

Cattle raising in Chile, A. OPAZO (*Vie Agr. et Rurale*, 2 (1913), No. 50, pp. 641-644, figs. 3).—Statistics showing the status of animal production in Chile are given as follows: Horses and mules 746,105, beef cattle 2,674,666, sheep 4,528,109, goats 746,739, and hogs 338,993. It is stated that the opportunities for improved horse and cattle breeding in Chile are good. The climate is moderate, the crops variable, and the pastures luxurious. The principal European breeds of horses are in evidence, and there have been importations of the Durham, Holstein, Lincoln Red, and Normandy breeds of cattle, thus improving the native stock.

Improvement of the local cattle, V. P. SUBRAMANIA MUDALIAR (*Jour. Madras Agr. Students' Union*, 1 (1913), No. 2, pp. 97-109).—An account of the local breeds of cattle native to India, their breed characteristics, and utility value.

Discussion on rearing calves, R. S. SETON (*Dairy*, 25 (1913), No. 300, pp. 327, 328).—In this address available data are summarized as to the use of separated milk with fat substitutes for rearing calves. Experiments are cited showing the value of cod liver oil and fish oil as substitutes for milk fat, and attention directed to a practice in which whey is heated just below boiling and the coagulated albumin collected as "fleetings." This was fed after the second week in increasing quantity to the milk allowance until in the sixth week the calves were receiving 8 quarts per head per day. Thereafter the quantity was gradually displaced by hay, linseed cake, bran, and rubbed oats. Other rations are also suggested.

Comparative value of distillery-waste mixed feeds for sheep, W. VÖLTZ, W. DIETRICH, and A. DEUTSCHLAND (*Landw. Jahrb.*, 45 (1913), No. 1, pp. 1-27).—In these experiments 2 sheep were fed on alternate periods of 8 days each (6 days intervening between periods) on hay alone; hay and a distillery waste, turf meal, and charcoal prepared feed; and hay and a distillery waste,

chopped wheat straw, prepared feed. The average digestibility of the feeds as determined by these experiments is shown in the following table:

Digestibility of distillery-waste mixed feeds by sheep.

Kind of feed.	Organic matter.	Protein.	Ether extract.	Nitrogen-free extract.	Crude fiber.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Hay alone.....	55.7	54.5	14.3	64.0	41.6
Hay and distillery waste, turf meal, and charcoal.....	50.4	68.2	13.2	57.0	29.1
Hay and distillery waste, wheat straw.....	65.0	74.8	41.3	69.1	51.8
Distillery waste, turf meal, charcoal.....	45.4	73.8	12.5	47.5	15.7
Distillery waste, wheat straw.....	73.2	83.8	63.7	74.5	60.6

The addition of turf meal and charcoal to the feed mixture apparently lowered its total digestibility, viz: Organic matter —5.9 per cent, protein —3.8, ether extract —0.4, nitrogen-free extract —9.9, and crude fiber +7.7. The use of turf meal as a filler in feed mixtures is thus condemned, while the advantages of the use of chopped wheat straw were made evident. Experiments by Pfeiffer are cited to show that while the value of chopped straw on the basis of its starch value in 100 kg. of dry matter is 2.01 marks, that of turf is —6 marks, or a difference of 8.01 marks. These results also correspond with those of Goy, in which it was found that the feeding of increasing amounts of sphagnum turf lowered the feeding value of its accompanying feeds.

The feeding of distillery waste materially increased the digestibility of the other materials in the mixture, thus making the apparent total digestible value of the distillery waste as follows: Organic matter 114.8 per cent, protein 91.2, ether extract 102.6, and crude fiber and nitrogen-free extract 148 per cent.

Feeding and care of breeding ewes, I. B. JOHNSON (*W. Va. Farm Bul.*, 1 (1913), No. 2, pp. 16, figs. 11).—This is a general discussion treating of the various breeds and their adaptability to West Virginia, selecting the farm flock, shelter and feeds for breeding sheep, management of the ewe and lamb, and sheep ailments.

Uncle Sam's Alaskan reindeer farm, H. M. TJERNAGEL (*Breeder's Gaz.*, 64 (1913), No. 25, pp. 1196, 1262, figs. 2).—During the period from 1892–1902, 1,280 reindeer were imported from Siberia, and in June, 1911, the statistics showed that there were 36,629 animals in Alaska distributed among 46 herds and belonging to 460 Eskimo owners. These reindeer are distributed among the natives by a system of apprenticeship, the native becoming absolute owner after an apprenticeship of 4 years.

The summer feeds consist of grass, weeds, foliage, and fresh shoots, and in winter of moss. The capacity for reindeer production in Alaska is said to be 10,000,000 head. The number of reindeer is increasing and the prospects for shipment of carcasses to the United States are good. The dressed weight of a 3-year-old steer is approximately 120 to 150 lbs. Reindeers are used as beasts of burden, the hide for clothing, and the does for milking purposes.

Meat production in swamps, P. B. POPEOE (*Jour. Heredity*, 5 (1914), No. 1, pp. 34–37, pl. 1, fig. 1).—In this article the adaptability of the Pigmy hippopotamus (*Hippopotamus liberiensis*) to southern swamp and marsh conditions is discussed. It is thought that these animals would readily adapt themselves to domestication and to the regions of the Temperate Zone. The weight of an adult male 10 years old is given as 420 lbs., that of a female 3 years old as 176 lbs.

Metabolism of matter and transformation of energy by fasting swine, F. TANGL (*Kisérlet. Közlem.*, 16 (1913), No. 4, pp. 482–507, figs. 4).—Experi-

ments were made with fasting swine to determine the minimum energy transformation for the maintenance of life.

According to these, in the case of lean growing swine, the transformation of energy was least at from 20 to 23° C., which is therefore the critical temperature. In the case of fattened animals the critical temperature may be about 17°. The transformation of energy determined at the critical temperature represents the minimum energy elimination of the swine, which according to the experiments averaged for fat swine 19.6 calories per kilogram, or 1,060 calories per square meter of body surface; for lean swine, 27.2 calories per kilogram or 1,100 calories per square meter. According to these figures the energy elimination per unit of body surface is independent of the fat content of the body.

On ovariectomy in sows, with observations on the mammary glands and internal genital organs, II, K. J. J. MACKENZIE and F. H. A. MARSHALL (*Jour. Agr. Sci. [England]*, 5 (1913), No. 4, pp. 418-423, pl. 1).—Continuing studies previously noted (E. S. R., 27, p. 875) it was found that black pigment is very frequently, but not invariably, present in the mammary tissue of Large Black, Berkshire, and other dark-colored sows. It is thought that by breeding from individuals in which this pigment is absent a strain may be built up of increased commercial value. It was further found that imperfect spaying, in which one, or a part of one, ovary is left behind, accounts for the frequent occurrence of spayed sows behaving as though they were "open."

Studies in comparative digestive physiology.—VI, On the course of drinking water in the stomach and the intestine of the horse, A. SCHEUNEER (*Pflüger's Arch. Physiol.*, 151 (1913), No. 7-10, pp. 396-406).—This is a continuation of studies previously reported (E. S. R., 28, p. 367). In this are given the percentages of water content in the forestomach, the fundus, and the pylorus portions of the stomach of the horse, when fed various quantities and proportions of hay, oats, and chopped straw. A study was also made of the course of and time required for the transport of water through the intestine.

[Studies on the normal intestinal flora of the horse], ANNA HOPFF (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 14 (1913), Nos. 4-5, pp. 307-315; 6, pp. 383-404).—Studies are reported of the normal intestinal flora found in the forestomach, fundus, pylorus, cecum, duodenum, colon, ileum, and rectum of the horse at periods immediately after, $\frac{3}{4}$, $1\frac{1}{2}$, and 3 hours after feeding, together with the degree of acidity or alkalinity detected.

Did the horse exist in America before this continent was discovered by Europeans? E. TROUESSART (*Sci. Amer. Sup.*, 76 (1913), No. 1981, p. 387).—This article has been previously reported from the original source (E. S. R., 30, p. 174).

Biological searchlight on race horse breeding.—VI, The heredity of blood-vessel breaking in the Thoroughbred, J. B. ROBERTSON (*Bloodstock Breeders' Rev.*, 2 (1913), No. 4, pp. 265-281).—In this article (E. S. R., 29, p. 773) the author traces the early history of blood-vessel breaking, and presents evidence to show the heritability of this character. It is shown that while only one runner out of every 400 each year, on the average, breaks a blood vessel, the affected individuals have a close common bond and are readily referable to common sources. Herod, foaled in 1758, is given as the prime, if not the sole, source of blood-vessel breaking in the English Thoroughbred. This phenomenon behaves as a recessive character, being carried in a latent form by either sex. The author points out that while ordinarily "a true recessive character, such as chestnut coat-color, only becomes patent in the individual when a determining factor for it has been inherited from both parents . . . in certain charac-

ters which depend on structural or physiological peculiarities and which are marked departures from normality, one intense dose of the usually latent or abnormal character may be sufficient to overcome the normal condition, which has been inherited from the sound parent."

"If there is any tendency to sex limitations it is but very feebly manifested as compared with human hæmophilia."

Barcaldine, a horse who was never beaten (*Bloodstock Breeders' Rev.*, 2 (1913), No. 4, pp. 287-290).—An account of Barcaldine and his influence on the British Thoroughbred. He was the sire of 174 winners, represented by many of the prominent individual winners. It is stated that no fewer than 64 of Barcaldine's offspring won as 2-year-olds. In 9 seasons at the stud he sired 249 living foals, an average of over 27 per season.

Army remounts, M. F. DEBARNVILLE (*Jour. U. S. Cavalry Assoc.*, 24 (1914), No. 100, pp. 686-689).—The author argues for the infusion of Arabian blood into our saddle-bred and half-bred mares, with the hope of adding stamina and improving the army remount. It is pointed out that in France 120 pure-bred Arabian stallions and 275 Anglo-Arabs are stationed in the government "haras." In Germany the remount depots of Trakehnen and Beberbeck use a number of Arabian stallions, the aim at these studs being to breed for the cavalry a half-bred having 50 per cent of English Thoroughbred blood, 25 per cent of Arabian blood, and 25 per cent of native blood. Austria and Russia likewise are using Arabian stock in improving the cavalry horse.

The weight carrying capacity, endurance, and speed of the Arabian horse are pointed out, and it is thought that in spite of their small size, by careful selection of large well-bred native mares bred to Arabian stallions, a good sized product would be obtained.

Horse breeding in Japan, S. MAKOTO (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 9, pp. 1326-1332).—The total number of horses in Japan is given as 1,564,643, or 3.15 per 100 inhabitants. To improve the breed of Japanese horses 3 studs for horse breeding, one rearing farm for foals, and 15 stallion depots have been established. For providing the remounts to the army there are 10 remount depots and about 3,500 yearlings are annually purchased.

The breeds of horses native to Japan have few distinguishing features. The introduction of Arabs, Thoroughbreds, Anglo-Arabs, Hungarians, Anglo-Normans, and Hackneys is aiding in improving the native stock. Horse shows and exhibitions have recently been instituted.

[Application of an electric stimulus to animal life], T. T. BAKER (*Jour. Roy. Soc. Arts*, 62 (1913), No. 3186, pp. 70-78, figs. 2).—An experiment is reported in which the author claims that an "intensive chicken house, consisting of 6 flats, each large enough to accommodate 75 chickens, was electrified by a large helix of heavily insulated wire wound round it in turns about 6 in. apart. The current was applied for 10 minutes every hour during the day. Six chickens out of a total of 400 died, showing a mortality of only 1.5 per cent, and the chickens were ready for market despatch in 5 weeks as against 3 months.

In another instance the increase in weight of the chickens in the electrified house was said to be about 35 per cent. Again "one set of chickens was grown against another and the electrified chickens were only given two-thirds of the food given (per chicken) to the others. After one month the weight per bird was the same. . . . In either case the chickens showed signs of their second feathers much earlier than usual."

The origin and destiny of cholesterol in the animal organism.—XI, The cholesterol content of growing chickens under different diets, J. A. GARDNER

and P. E. LANDER (*Proc. Roy. Soc. [London], Ser. B*, 87 (1914), No. B 594, pp. 229-236).—This is a continuation of studies previously noted (E. S. R., 28, p. 462). Three diets were fed to different lots of day-old chicks, and analyses made at the end of 1, 2, 3, and 4 weeks for cholesterol content of the chicks.

With chicks fed on an ordinary diet "the total cholesterol decreases by about 15 per cent during the first week, and then increases again during the second week to within about 6 per cent of the value in the day-old chick. . . .

"In the case of animals fed on the extracted diet, there is a decrease in the total cholesterol during the 2 weeks, but the decrease during the first week is nearly double that in the second. . . . In the case of the animals fed on extracted food plus cholesterol, the total cholesterol increases during the two weeks, more markedly in the second than in the first. . . . The cholesterol content of the chickens thus appears to depend on the cholesterol content of the diets, but there is nothing in the figures of the first 2 weeks to indicate that in the growing animal the organism can synthesize cholesterol."

Fatty acids of hen's eggs, V. H. MOTTRAM (*Jour. Physiol.*, 47 (1913), No. 4-5, pp. XVIII, XIX).—In tests involving the analysis of over 50 eggs, the following observations were made:

"The mean iodine value of the fatty acids from eggs is fairly constant no matter what the locality and breed. This is true even if the eggs have been allowed to age somewhat. . . . Nevertheless, in any one breed and locality, there is considerable variation from the mean. . . . Hens, even from the same stock, fed on the same diet have individual peculiarities. One will deposit high iodine value fatty acids, another low. . . . There is a remarkable constancy in the iodine value of any one hen. . . . Infertile eggs of widely differing iodine values approximate in iodine values on incubation. . . . A similar observation has been made on incubated fertile eggs. As a whole incubation affects the iodine values but little. There is, however, evidence in the case of a hen laying low iodine value eggs of a rise in iodine value during the first week of incubation."

Egg records for the year 1912-13 (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 14 (1913), No. 1, pp. 86-101).—Egg-laying records for 156 flocks including 4,859 birds are reported. The five highest breeds in laying capacity were: Minorcas, Rhode Island Reds, Brown Leghorns, Black Leghorns, and White Leghorns. The average number of eggs per flock laid for the year by all breeds was 112.5 per hen; the highest number laid 232.9, the lowest 50.1.

Chinese egg products, C. E. GAUSS (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 3, pp. 46, 47).—It is reported that the United States takes about 10 per cent of China's egg products, both hen and duck eggs being used. The eggs are broken and the albumin separated from the yolk. The albumin is beaten, strained, and finally dried at a temperature of 130°. The egg yolk is well beaten, placed in cement tanks for 3 days, 2 per cent boric acid added, put in casks ready for export, and shipped in liquid form.

The British standard of perfection for Indian Runner ducks (1913, *Amer. Ed.*, pp. 8).—A description of the general breed characteristics and detailed points desired in the Indian Runner breed of ducks.

Carp breeding in rice fields in Italy, F. SUPINO (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 9, pp. 1332-1335).—Success is reported in Italian experiments in carp breeding in rice fields.

The fry are first raised in a spawning pond, and from 800 to 1,600 per acre put into the rice field according to conditions. When turned into the field the fry weigh 1 oz. per thousand; after 3 months fish weighing 3½ to 7 oz. can be found. The presence of carp in the field in no way hinders the usual cultivation

operations of the rice, and they are actually beneficial to the rice crop. During winter they are put into a pond or tank, 85 lbs. of fish to each 3-ft. cube, and the following summer again turned into the rice field, about 80 per acre. At harvest time each fish weighs 2 lbs. or more. If kept during a third summer they reach nearly 5 lbs. in weight. An acre of rice field may yield 90 lbs. of carp.

It is thought that carp may be used in the control of malaria since they feed on the eggs and larvæ of mosquitoes. The trout-perch was tried in rice fields and though it did not reach the same size as the carp, its flesh was of better quality.

DAIRY FARMING—DAIRYING.

Open stables versus closed stables for dairy animals, S. S. BUCKLEY (*Maryland Sta. Bul. 177 (1913), pp. 219-250, figs. 3*).—As the result of 3 seasons' observations made during the fall and winter months, the advantages claimed for open stables for dairy animals are the lower cost of construction, equipment, and labor. The cost of production of milk, based on the amount of food consumed, is also slightly less. The effects of extreme low temperatures are practically negative in reducing the flow of milk. The manure is better preserved owing to the thorough mixing of solids and liquids with the litter. The cleanliness of the cows and the bacterial content of the milk produced are more favorable. There are also the advantages of fresh air and light, a separate milking room, and less danger from slipping on floors. A greater percentage increase in body weight was obtained in the tests.

The maximum and minimum temperatures for each week during the winter months were taken for both open and closed stables, and while the differences were at times very great, no greater variation in the flow of milk was observed from the cows exposed to a temperature of -14° F. in the open stable than in those cows in the closed stable which were exposed to a temperature of $+14^{\circ}$. It is stated that there is no instance in which there has been a decided decrease in production of milk, temporary or permanent, which can be attributed to low temperature or to sudden fluctuation in temperature, unless at the same time there was exposure to rain.

The feeding and milking operations in the open stable are described as follows: "The cows occupy the open spaces of the stable during the time they are housed, and have access to the mangers for roughage, and to a plentiful supply of drinking water. The floor is abundantly supplied with bedding in the fall of the year, and as it becomes worked into the droppings, just enough new litter is supplied to keep the surface in good condition. After each removal of manure the floor is well supplied with fresh litter and the process of caring for it repeated.

"At milking time the cows are all driven into one end of the stable and the bars or gateway closed. Three cows are then allowed into the milking room (space for more than 3, in a stable of 30, is recommended) and fed grain. These are then milked and turned into the opposite end of the stable, directly from the milking room. A second set is then allowed in the milking room, fed, milked, and turned out. This is continued until all are fed, milked, and turned out. The bars or gates are then opened and the cows given the freedom of the stable until the next milking time."

A comparison between the bacterial content of milk drawn in the closed stable and in the milking room of the open stable, R. W. LAMSON (*Maryland Sta. Bul. 177 (1913), pp. 251-262*).—From the comparison reported it was found that while only general conclusions could be drawn there seemed to be quite an

advantage in favor of the open stable as a place to produce milk of a low germ content. The germ content of the air in the milking room of the open stable was less than in the closed stable, and fecal contamination of milk, as indicated by a fermentation of 25 per cent or more in a lactose-bile medium, was no greater than in the closed stable, where the cows require more careful attention. The individuality of the animal appeared to be an important consideration in producing milk of low bacterial content.

The sanitary significance of body cells in milk, R. S. BREED (*Jour. Infect. Diseases*, 14 (1914), No. 1, pp. 93-99).—The conclusions drawn from the studies made of the cellular content of milk are summarized by the author as follows:

"(1) Normal milk contains cells derived from the body of the cow which are of 2 entirely different types: (a) White blood corpuscles which are largely of the polynuclear and polymorphonuclear type; these cells make their way into the milk by passage through the epithelial lining of the secreting portion of the gland, possibly, also, through the epithelial lining of the ducts of the gland; (b) epithelial cells, nuclei, and cell débris discharged from the epithelial lining of the secreting portion of the gland and possibly also from the ducts.

"(2) The number of these cells in apparently normal milk is exceedingly variable even in the milk from the same cow. The variation in the number of cells in the milk from the different quadrants of the udder is almost as great as the variation in number of cells in the milk of different animals. Apparently the strippings always contain a greater number of cells than the milk from the earlier part of the milking.

"(3) It is very common to find milk that contains so few cells that they can scarcely be counted with the method of examination used, i. e., less than 5,000 per cubic centimeter, but milk containing one or more millions of these cells per cubic centimeter is met with frequently. The highest cell count which has been found in this work was in the case of the strippings from one-quarter of the udder of a cow 8 days after calving where the milk showed the enormous count of 54,300,000 cells per cubic centimeter. Nevertheless, this milk was of an entirely normal appearance and careful bacteriological examination of the udder showed no evidence of streptococcal infection. This milk had an entirely normal taste and caused no evil after-effects.

"(4) Out of 122 individual cows whose milk has been examined, 59 have been found to give cell counts under 500,000 per cubic centimeter, 36 gave counts between 500,000 and 1,000,000 per cubic centimeter, and 27 gave cell counts over 1,000,000 per cubic centimeter. The milk of all of these cows was normal in appearance and was sold or used by their owners, who had every reason to suppose that the milk was normal milk.

"(5) There are no satisfactory data at hand to show whether there is, or is not, a relation between high cell counts and any of the following: Streptococcal infection of the udder or other pathological conditions of the udder, colostral milk, milk from cows that are nearly dry, in heat, or in poor condition of flesh, etc. Such evidence as we have indicates that it is not at all likely that any of these conditions may be recognized by cell counts alone, especially in samples of market milk which consist of a mixture of the milk from several cows."

The author believes that while "it is entirely possible that some of the striking variations in numbers have a sanitary significance, as pathological conditions would certainly affect the discharge of these body cells . . . [it is] impossible to make even a guess as to the final conclusions regarding the significance of the variations in number and character of the cells."

Creamery bacteriology, O. JENSEN (*Die Bakteriologie in der Milchwirtschaft*, Jena, 1913, pp. 182, figs. 60).—Part 1 of this book treats of the micro-organisms

and the fermentation processes involved in creamery practice, of the types of bacteria, and of the fungi of yeasts and molds; part 2 deals with sanitation in the creamery, the normal and abnormal microflora of milk, the preservation of milk and method of handling for direct consumption, the processes of milk souring in the creamery, the normal and abnormal microflora of butter, the bacteriology of cheese making, and the judging of milk.

Modification of the composition of cow's milk by medicinal means, O. LANZONI (*Clin. Vet. [Milan] Rass. Pol. Sanit. e Ig.*, 36 (1913), Nos. 1, pp. 11-23; 2, pp. 58-69).—Experiments by the author indicate that the composition of milk may be materially modified by the effects of such drugs as sodium sulphate, magnesium sulphate, rhubarb, aloes, and arsenic. This alteration may consist in a loss of nutrients, due to a decrease in the total solids, or in an excess of casein, rendering the milk less digestible.

A study of the milk of Porto Rican cows, W. J. LUCAS, R. DEL VALLE SÁRRAGA, and J. R. BENITEZ (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 1, pp. 22-24).—This is a report of work giving the first of a series of analyses to be made for the purpose of determining a standard for Porto Rican milk.

The native Porto Rican cow gives only a small yield of milk, due to a deterioration of the strain, improper milking methods, and insufficient food. It was found that the milk may vary within wide limits as regards total solids and fat content and may run exceptionally high in solids-not-fat, ash, lactose, and refraction of copper serum. Guinea grass seems to be the best adapted as a pasture for cows, the fat content averaging considerably higher in the milk from cows so fed.

Seventh annual report of the B. C. Dairymen's Association (*Ann. Rpt. B. C. Dairymen's Assoc.*, 7 (1912), pp. 83, pls. 4, figs. 7).—Papers included in this report are as follows: The dairy sire, improving the dairy herd, business methods for the dairy farmer, dairy inspection, management of the dairy cow, community breeding, cow testing associations, and milk and its products in relation to public health.

Report of milk inspector, 1912, J. O. JORDAN (*Ann. Rpt. Health Dept. Boston*, 41 (1912-13), pp. 71-141, pls. 6, figs. 2).—This report relates to the consumption of milk in the city of Boston, the production of certified and inspected milk, sanitary precautions, bacteriological and sanitary inspection methods and results, investigation of milk contaminated with pus and streptococci, and examination of ice cream samples.

The municipal regulation of milk supply, E. O. JORDAN (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 26, pp. 2286-2291).—In a study made of the municipal regulations of the milk supply of cities in the United States of over 25,000 population, it was found that the requirement of a permit or license is practically universal in all cities of over 50,000 inhabitants, while some of the cities in the 25,000 to 50,000 group require no permit and a considerable number have no ordinance regulating the sale of milk in any way. Dairy farm inspection of some sort is carried on by the great majority of cities, though the frequency of inspection is very irregular. Thirty-three per cent of the cities require that the tuberculin test be applied to herds furnishing milk. Bacterial standards for raw milk ranging from 100,000 to 1,000,000 have been established by the large majority of cities with over 100,000 population, while cities in the 25,000 to 50,000 group usually lack these requirements. About 30 per cent of the cities with over 100,000 population have half or more of their milk supply pasteurized. There is a general absence of any regulations dealing with the pasteurizing process.

It is shown that in the ten years 1902-1912 there has been an average increase in the retail price of milk in all parts of the United States of from 2 to 3 cts. a

quart; an extensive development in methods of supervision and an increase in the amount expended for supervision; and a noteworthy change in the growth of the process of pasteurization. The need of uniform and efficient milk ordinances and the proper adjustment of state and local control boards is discussed.

[Report of the dairy commission] (In *Nebr. Food, Drug, Dairy and Oil Com. Laws [Lincoln]*, 1913, pp. 12-16, 42-45, 69-71).—A text of the Nebraska laws and regulations pertaining to the sale of milk, imitation butter, and the sampling, weighing, and grading of milk samples.

[First, second, and final reports of the Irish Milk Commission, 1911] (*Irish Milk Com., First Rpt. (1911)*, pp. IV; App., pp. VII+405; *Second Rpt. (1911)*, pp. IV; App., pp. VI+363; *Final Rpt. (1911)*, pp. VI+61; App., pp. VII+220).—These reports with their appendixes relate to the alleged scarcity in the supply of milk in some parts of Ireland, the causes of the deficiency, where it exists, its effect upon the public health, the means whereby the deficiency may be remedied, the dangers of contamination and infection in the milk supply, and the methods best adapted to guard against these dangers. The establishment of milk depots and cow-testing associations and the provision of pails for the grazing in common of laborers' cows are recommended.

Proceedings of the Official Dairy Instructors' Association (*Proc. Off. Dairy Instrs. Assoc.*, 5-7 (1910-1912), pp. 146, figs. 5).—This gives the reports of the committees on dairy score card, experimental work in dairy manufactures and milk production, standards for dairy products, official methods of testing dairy products, judging dairy cattle, legal minimum of butter fat in butter, courses of dairy instruction, and lime and other alkali in the manufacture of butter.

Stilton cheese, MISS G. N. DAVIES (*Jour. Agr. [New Zeal.]*, 7 (1913), No. 5, pp. 502-510).—Methods for the manufacture of the high-priced variety of Stilton cheese are described. This cheese is known by its drab-colored, wrinkled skin, its mold throughout the cheese, and its flavor, which is partly due to the mold. Success in its manufacture depends largely upon the normal growth of the blue mold (*Penicillium glaucum*) within the cheese. Stilton cheese is not pressed, the whey being removed by gravitation and evaporation.

Ripening of sheep cheese, E. DE' CONNO (*Atti. R. Ist. Incoragg. Napoli*, 6. ser., 64 (1913), pp. 81-112).—This treats of the composition of sheep cheese and the chemical changes undergone in the process of ripening.

Wisconsin cheese factories, creameries, and condenseries by counties and dairy statistics, J. Q. EMERY (*Madison, Wis.: Dairy and Food Com.*, 1913, pp. 67, pls. 2, figs. 6).—A statistical review of the butter, cheese, and milk industry in the various States, and a list by counties of the cheese factories, creameries, skimming stations, and condenseries in Wisconsin.

VETERINARY MEDICINE.

[Animal diseases in the Anglo-Egyptian Sudan] (*Rpt. Wellcome Research Labs. Gordon Mem. Col. Khartum*, 4 (1911), A. Med., pp. 41-56, 76-107, 343-361, pls. 6, figs. 15).—Several papers relating to diseases of animals are here presented. Animal trypanosomiasis in the Anglo-Egyptian Sudan (pp. 41-56) are dealt with by W. B. Fry and Spirochetosis of Sudanese Fowls (pp. 76-111) by A. Balfour. Under the heading of Veterinary Notes (pp. 343-352) A. Balfour presents observations regarding epizootic lymphangitis of equines, coccidiosis in cattle, piroplasmosis, anaplasmosis, and filariasis in the horse, camel, and hare. Acid-fast Bacilli in the Lung of a Camel (pp. 352, 353) and Interstitial

Pneumonia in a Camel's Lung (pp. 353, 354) are considered by R. G. Archibald; and Coccidiosis of the Intestine in the Goat (pp. 355-359) and A Few Notes on the Protozoa Parasitic in *Bufo regularis* in Khartum (pp. 359-361) are presented by A. C. Stevenson.

Is the specificity of the anaphylaxis reaction dependent on the chemical constitution of the proteins or on their biological relations?—II, The biological reactions of the vegetable proteins, H. G. WELLS and T. B. OSBORNE (*Jour. Infect. Diseases*, 12 (1913), No. 3, pp. 341-358).—In previous work (E. S. R., 25, p. 9) it was shown that zein, the alcoholic-soluble protein of corn, did not produce an anaphylaxis reaction in animals sensitized with gliadin or hordein. It was, however, found that gliadin from either wheat or rye interacted as if they were one and the same protein.

"Guinea pigs, sensitized with gliadin from wheat or rye, give strong anaphylactic reactions with hordein from barley, but these are not as strong as the reactions obtained with the homologous protein. Similar results are obtained if the sensitizing protein is hordein and the second injection is gliadin. We have here a common anaphylaxis reaction developed by two chemically distinct, but similar, proteins of different biological origin, thus indicating that the specificity of this reaction is determined by the chemical constitution of the protein rather than by its biological origin. This is in harmony with the fact that chemically closely related proteins have, as yet, been found only in tissues that are biologically nearly related.

"Complete protection to subsequent injection of the homologous protein was not afforded by a reaction to the heterologous protein, thus indicating the presence of two or more individual proteins in the preparations of gliadin and hordein, one of which is common to both, or else the presence in gliadin and hordein of both common and specific reactive groups. The chemical evidence is in favor of the latter conclusion. The foregoing indications are supported by saturation experiments, which show that when guinea pigs are sensitized with either gliadin or hordein, and then saturated with the heterologous protein, they still react strongly when injected with the homologous protein.

"Gliadin and glutenin react anaphylactically with one another, although chemical comparisons have shown them to be proteins of distinctly different types. Evidence was obtained that the reactions between these proteins should not be ascribed to contamination of the preparations with one another, i. e., to an incomplete separation of the two. The conclusion appears justified that these chemically distinct proteins contain common reactive groups. Guinea pigs sensitized with glutenin do not react anaphylactically with hordein, thus showing that the reaction between gliadin and glutenin is not caused by an incomplete separation of these latter proteins, but by reactive groups common to gliadin and glutenin, but absent from hordein.

"From the results of these experiments it seems probable that the entire protein molecule is not involved in the specific character of the anaphylaxis reaction, but this is developed by certain groups contained therein, and that one and the same protein molecule may contain two or more such groups. It may well be that the intact protein molecule is involved in the reaction (for there is but little evidence that anything less than an intact protein molecule is capable of producing the typical reaction), but that certain groups determine the specificity. Such a conclusion can not be accepted as final until we have some means whereby the chemical individuality of a protein can be established. Until then the possibility will remain that our so-called pure preparations of protein consist of mixtures, or combinations, of proteins which have thus far resisted all efforts to separate them. In this latter case the reactions

here attributed to groups in one protein molecule might be caused by individual proteins contained in the preparations made by the methods now in use.

"These experiments demonstrate that the 'group reactions,' characteristic of biological reactions between closely related species which usually have been interpreted as indicating the presence in related organisms of identical as well as distinct proteins, can really be exhibited by single isolated proteins from related organisms. In other words, biological relationship and chemical relationship seem to be much the same.

"Attention is also called to certain other observations: (a) That animals sensitized with two proteins will, as is well known, react with either, and that after recovery from reaction with one protein the reaction given with the second protein is less severe than it would be if the animal had not already passed through an anaphylactic intoxication; (b) that after injection with an intoxicating dose of a vegetable protein, another injection with the same protein 24 to 72 hours later, when the animal is usually insusceptible, so far as constitutional symptoms are concerned, often produces a severe, transient peritoneal irritation, which seems to be in the nature of a specific local reaction."

The milk-rennet inhibition test, K. PALLMANN (*Die Milch-Labhemmprobe. Inaug. Diss., Tierärztl. Hochsch. Stuttgart, 1912; abs. in Berlin. Tierärztl. Wehnschr., 29 (1913), No. 22, p. 405*).—Normal milks, milk from individual cows, and mixed milks show an inhibition or rennet action in dilutions from 1:1,000 to 1:1,500; most milks, however, coagulate at high dilutions. Variations between 1:1,000 and 1:4,000 occur. With colostrum the coagulating power is only strongly increased up to the third or fourth day post partum. After this period it returns to the point where the coagulating power resembles that of normal milk. On this account the test can not be relied upon as an indicator of a newly lactating animal. The milk from animals in the later stages of lactation almost always shows a diminished coagulating power.

A marked diminution or absolute loss in coagulating power is present in high-grade mastitis, especially in infectious mastitis; consequently the test can be used for detecting pathologic mammary secretions, particularly in conjunction with the milk (leucocyte) test. The factor which stands in the way of the use of the method for practical milk control is the difficulty of obtaining a standard rennet solution (*E. S. R., 29, p. 504*) and the cumbersomeness of the procedure.

The nature of the Kurloff body: A stage in the development of the eosinophil leucocyte, H. W. ACTON and R. KNOWLES (*Indian Jour. Med. Research, 1 (1914), No. 3, pp. 523-531, pl. 1*).—"The Kurloff body is found in the bone marrow of widely different animals, birds, amphibians, and mammals, and is not confined to the guinea pig. It can not, therefore, be a parasite. It is a phase in the development of the eosinophil cell and is identical with the structure known as an archoplasmic vesicle. The Kurloff bodies are, therefore, the bone marrow representatives of the granules of the eosinophil leucocytes, and their appearance in the peripheral blood of the guinea pig or other animal may be associated with helminthic infections. The Kurloff body is formed by the nucleolus in an exactly similar manner to other zymogen granules. We are, therefore, able to confirm Ehrlich's and Kurloff's view as to the nature of these bodies. They contain Secretin-Stoff. The eosinophil granules are derived from the nucleolus and are of the nature of zymogen granules. The phases in development seen in these archoplasmic vesicles from the Initial Körper to the formation of the spireme stage coincide exactly with the stages described by E. H. Ross^a in the development of the *Lymphocytozoon cobayæ*, and by Hartmann and Prowazek for *Chlamydozoa*."

^a Proc. Roy. Soc. [London], Ser. B, 85 (1912), No. B 576, pp. 67-72, pl. 1.

Cyanogenesis under digestive conditions, S. J. M. AULD (*Jour. Agr. Sci. [England]*, 5 (1913), No. 4, pp. 409-417; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 12, pp. 1878-1880).—"Under digestive conditions cyanogenesis is likely to be inhibited by acids and alkalis, digestive juices, cellulose, glucose, and molasses, salt, and many other feeding stuff constituents and adjuncts. Owing to the time the food remains in the digestive tract before coming to the true stomach or the acid secreting portion of the stomach, normal inhibition is caused by the alkaline character of the salivary juices. This is likely to be the chief cause of the innocuous character of linseed cake.

"In the case of sheep fed with linseed cake shortly before being killed small amounts of hydrocyanic acid were to be found, chiefly in the rumen. Cyanogenetic feeding stuffs are most likely to be poisonous when fed with acid-containing or acid-producing foodstuffs, or where the hydrocyanic acid is preformed, as in the case of an improperly made linseed gruel. The small quantities of hydrocyanic acid normally produced from cyanogenetic feeding stuffs may possibly have a strongly beneficial action."

A bibliography of 15 titles is appended.

Investigations in regard to the relation of pseudoanthrax bacilli to anthrax bacilli with the precipitation method, W. PFEILER and L. DRESCHER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), No. 7, pp. 391-401).—It has been shown by others that a specific reaction can be obtained with non-specific extracts prepared from material containing pseudoanthrax bacilli. With the object of determining what relationship exists between anthrax and pseudoanthrax bacilli from the serological standpoint, and especially with regard to the application of the results obtained to actual practice, experiments were made with anthrax bacilli, pseudoanthrax bacilli (*Bacillus anthracoides*), and a strain of *B. mesentericus*.

The reactions obtained with the extracts of pseudoanthrax strains and specific anthrax serum were in some cases weaker and in other cases stronger than those obtained with true anthrax extracts. Some of the pseudo extracts seemed to give a more marked reaction when used in a greater dilution than the anthrax extracts. The experiments seem to show that it is hard to distinguish between real anthrax organisms and pseudoanthrax.

The meiostagmin and epiphanin reactions in the diagnosis of carcinoma, W. H. BURMEISTER (*Jour. Infect. Diseases*, 12 (1913), No. 3, pp. 459-471, figs. 16).—"A decidedly negative meiostagmin reaction is of more value than a positive one and may be considered of some weight in ruling out carcinoma. A moderately or even strongly positive reaction is not necessarily indicative of malignant tumor.

"The epiphanin reaction is valueless in the diagnosis of malignant tumors. The range of error determined by the blind titrations in a measure also explains the results obtained by other workers who have employed this reaction in the diagnosis of diseases other than carcinoma."

A note on some experiments performed with a view to finding out the period before symptoms during which the saliva of an animal incubating rabies is infective, J. A. CRICKSHANK and R. E. WRIGHT (*Indian Jour. Med. Research*, 1 (1914), No. 3, pp. 532-535).—"It is difficult to infect rabbits and guinea pigs either intramuscularly or subdurally with the saliva of dogs or guinea pigs in the presymptomatic stage of rabies. In one case the saliva of a dog was infective 3 days before the animal showed symptoms. Even when the symptoms of rabies have manifested themselves it is still difficult to demonstrate the infectivity of saliva experimentally. This suggests that the bites of rabid dogs, even under optimum conditions for infection, may not infect

because the saliva is not virulent. Suspensions of the salivary glands themselves are much more certainly infective under experimental conditions than the saliva derived from them. This is more especially the case for the submaxillary gland. Negri bodies are not always demonstrable in the brains of experimental rabid animals, although they may become so after subpassage."

About the occurrence and the combating of rinderpest at the present time, P. KNUTH (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), Nos. 5, pp. 273-293; 6, pp. 356-369).—A review of the literature pertaining to this topic, accompanied by a bibliography embracing 51 titles.

Trypanosomes of game and domestic stock, A. KINGHORN and W. YORKE (*Ann. Trop. Med. and Par.*, 7 (1913), No. 2, pp. 227-238).—"Trypanosomes are of frequent occurrence in game and domestic stock in northeastern Rhodesia. As a conservative estimate the percentage of big game infected with trypanosomes pathogenic to man and domestic stock may at Nawalia (Luangwa Valley) be placed at 50, and at Ngoa (Kongo-Zambezi watershed) at 35. At Nawalia 6 species of trypanosomes were isolated from game and domestic stock, viz, *Trypanosoma rhodesiense*, *T. vivax*, *T. nanum*, *T. pectorum*, *T. montgomeryi*, and *T. multifforme*; whilst at Ngoa 5 species were found, viz, *T. rhodesiense*, *T. vivax*, *T. nanum*, *T. pectorum*, and *T. tragelaphi*."

"The results of examination of over 400 monkeys, wild rats, and mice were invariably negative."

Tubercle bacilli in the circulating blood of bovines artificially infected with pure cultures of the tubercle bacillus, W. BINDER (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 29, pp. 513-519).—The investigations here reported were made with 9 animals which had been treated with pure cultures of the bovine tubercle bacillus for some other experiments. For detecting tubercle bacilli in the circulating blood the Stäubli-Schnitter method and the Kurashige modification thereof were used, but the former method is preferred.

The author concludes that tubercle bacilli do occur in the circulating blood of tuberculous bovines, contrary to the findings of Schroeder and Cotton (*E. S. R.*, 22, p. 83), although in none of the cases were very many organisms found in a microscopic field. In the severest cases only 3 to 5 organisms per field were noted. When intravenously injected the bacilli were noted in the blood from 3 to 11 days later, then they disappeared and reappeared after 17 to 30 days. While it was easier to detect the tubercle bacilli in severe cases, no prognostic significance, the author says, can be attached to the finding of tubercle bacilli in the circulating blood.

Tubercle bacilli in the circulating blood, E. ROSENBERG (*München. Med. Wchnschr.*, 60 (1913), No. 8, pp. 404, 405; *abs. in Deut. Med. Wchnschr.*, 39 (1913), No. 11, pp. 522, 523).—In the blood of nearly all cases of tuberculosis (pulmonary and surgical cases in man) acid-fast bacilli resembling the tubercle bacillus were noted. They were never found in the blood of normal subjects.

The detection of tubercle bacilli in the circulating blood, E. KAHN (*München. Med. Wchnschr.*, 60 (1913), No. 7, pp. 345, 346; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 22, p. 402).—Attention is called to the fact that a mere microscopical examination of the blood is not an adequate means for detecting the presence of tubercle bacilli in the circulating blood. The animal test is the most certain method.

Chemotherapy of tuberculosis with gold preparations, A. FELDT (*Deut. Med. Wchnschr.*, 39 (1913), No. 12, pp. 549-551; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 22, p. 402).—The preparations used were combinations of cantharidin and gold, and for their preparation cantharidinethylen diamine, which is a nontoxic preparation, and gold cyanide were employed. Cantharidin, which is capable of producing a reaction in tuberculosis and in other inflammatory

areas, while toxic has no germicidal properties. All the preparations produced a marked local reaction (secondary tuberculin reaction), but when given intravenously to rabbits yielded favorable results. The life of these animals was not only prolonged for many months but, in addition, an increase in weight was produced. No improvement was noted in guinea pigs which received the preparations subcutaneously.

The treatment of bovine mammitis by serum, B. EGGINK, JR. (*Tijdschr. Veeartsenijk.*, 39 (1912), No. 5, pp. 194-197; *abs. in Ann. Méd. Vét.*, 61 (1912), No. 6, pp. 332-334; *Vet. Rec.*, 25 (1912), No. 1253, p. 18).—The use of an anti-streptococcic serum as a treatment for acute and fairly well advanced, non-purulent cases of mammitis gave good results.

[Cattle ticks in Costa Rica], J. E. VAN DER LAAT (*Bol. Fomento [Costa Rica]*, 3 (1913), No. 4, pp. 259-263, figs. 2; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. B, No. 9, p. 159).—The author describes the method employed in dipping ticky cattle in Costa Rica, where the practice is said to be well established on a large number of large estates.

The tick problem in New South Wales, M. HENBY (*Agr. Gaz. N. S. Wales*, 24 (1913), No. 10, pp. 829-837).—A general discussion of the situation in New South Wales.

Abortion in sheep, J. McFADYEAN ET AL. (*Rpt. Dept. Com. Bd. Agr. and Fisheries [Gt. Brit.], Epizootic Abortion, 1913, pt. 3, pp. 12; App., pp. 33, pl. 1; abs. in Vet. Rec.*, 26 (1913), No. 1329, p. 401).—This is the third and final report of the committee appointed to inquire into epizootic abortion (E. S. R., 24, p. 388). An appendix to the report, by J. McFadyean and S. Stockman, issued as a separate publication, contains a detailed account of the experiments and observations upon which the report is based. This report, which forms the first account of a hitherto unrecognized disease, summarizes all that is known regarding it.

Though *Bacillus abortus* is known to be capable of producing abortion in sheep it is not the common cause of the ovine disease in Great Britain. The only specific form of ovine abortion which the committee met with is due to a vibronic organism. Descriptions are given of the morphological and cultural characteristics of this organism which resembles the spirochete in appearance though not in its cultural requirements. Experimentally this vibrio may cause abortion in cows as well as in sheep and two naturally occurring outbreaks of vibronic abortion in cows were met with, one in Ireland and one in Wales.

The alimentary tract appears to be the most common natural channel of infection. Usually, for some time before abortion takes place, there is an infective discharge from the vulva. The disease is enzootic rather than epizootic in character, not spreading rapidly from farm to farm. "The symptoms are not very distinctive—perhaps a sanious, mucoid vulvar discharge before abortion is the most significant one. Usually abortion takes place at an advanced period of pregnancy. Very often the fetus has died at a much earlier stage, though lambs may be born alive from an infected uterus at or about full time. Often both fetus and membranes are putrid when expelled, and metritis, which may be fatal, is not a rare complication. At post-mortem, in the later stages, the uterus shows edema and congestion, with an abundant exudate between chorion and uterus. All the uterine contents—exudate, membranes, and fetus—contain the vibrio, and are virulent.

"The spread of the disease under natural conditions requires further investigation; but it is certain that an ewe may discharge vibrios from the vagina, and thus be infective, long before showing any signs of impending abortion. It is doubtful whether the ram has much or any importance as a factor in contagion. There is also much still to be learned as to how long the

vibrio can live outside the body. It seems to soon lose its pathogenicity when cultivated; and serious outbreaks of the disease do not usually occur on the same farm year after year. But nevertheless there is some evidence that the microbe may exist, saprophytically or otherwise, outside the body of the sheep. The symptoms, circumstances, post-mortem lesions, and microscopical findings are all of importance in diagnosis. The agglutination test promises to be of practical value here, and the complement fixation test is also being worked upon."

The committee advance various recommendations for prevention, including destruction of virulent material, isolation of aborting ewes and disinfection of their genitals, and the avoidance of penning ewes together in close proximity before lambing. Thus far the committee do not consider legislative measures applicable to the disease.

A new (?) strongyle causing parasitic gastritis in a goat, J. B. BUXTON (*Vet. Jour.*, 70 (1914), No. 464, pp. 89-94, figs. 5).—The nematode here considered closely resembles the strongyle of Axe, which is found in the stomach of the horse but apparently causes no ill effects, and the *Strongylus gracilis* of cattle and sheep, from which, however, it differs in several respects.

The detection of erysipelas in hogs with the precipitation method, L. DRESCHER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 5 (1913), No. 4, pp. 322-331; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 27, pp. 489, 490).—As a result of the experiments conducted, the conclusion is reached that Ascoli's thermoprecipitation reaction when used for diagnosing erysipelas in hogs is without value for practical purposes.

About the detection of antibodies in the blood of horses immunized with voldagsen (hog cholera) bacilli and hogs affected with voldagsen cholera, W. BUCHAL (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 5 (1913), No. 4, pp. 263-276; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 27, p. 490).—After pointing out that bacteria present must also be considered when studying hog cholera, the results of experiments made with the complement fixation, agglutination, and precipitation tests are reported.

In conjunction with the tests some experiments were made with reference to the valuation of immune sera produced in two horses which were previously treated with voldagsen strains of bacteria. It was noted that the sera of both horses contained agglutinins, precipitins, and complement fixing substances, and one of the horses showed a much greater antibody formation than the other. No bacteriolysins were produced. The protective value of the sera for mice was 0.1 cc. and upwards.

The sera of the hogs which had passed through a voldagsen or other infection did not show the same constancy in regard to agglutinating, precipitating, or complement fixing substances as the horse sera. Incidentally it was found that the sera of sound hogs contained a normal precipitin for the voldagsen precipitinogen. This normal precipitin was noted in horse serum also.

A case of the septicemic form of hog cholera in German Southwest Africa, SCHMID (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), No. 6, pp. 353-355).—A description of the case with a statement of the findings on autopsy.

Trichinosis, J. M. VAN COTT and W. LINTZ (*Jour. Amer. Med. Assoc.*, 62 (1914), No. 9, pp. 680-684, figs. 2).—The authors report that they have demonstrated for the first time the presence of living trichinae in the cerebro-spinal fluid in vivo. Salvarsan as shown in cases treated is useless as a therapeutic agent.

Cerebro-spinal meningitis ("forage poisoning"), J. R. MOHLER (*U. S. Dept. Agr. Bul.* 65 (1914), pp. 14).—The data here presented have been previously noted from another source (*E. S. R.*, 28, p. 886.)

[Mal de caderas in British Guiana] (*Agr. News [Barbados]*, 12 (1913), Nos. 500, p. 345; 304, p. 411).—This note relates to the occurrence of a disease in

British Guiana, which is in all probability mal de caderas. This disease, provisionally described in the report of the government veterinarian as cerebrospinal meningitis, has been prevalent among mules and horses in certain districts of Berbice, British Guiana.

Tests in regard to the diagnostic value of the ophthalmo reaction in glanders, LORENZ (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 14, pp. 252-255).—A report in regard to tests made according to the specifications suggested by Fröhner, namely, 0.05 gm. mallein siccum (Foth) dissolved in 4.5 gm. of a 0.5 per cent carbolic acid solution. The solution was prepared on the day it was to be used. Several drops were instilled in the conjunctival sac of the right eye, and in the left eye a few drops of a 0.5 per cent carbolic acid solution were introduced. This procedure was found to be especially valuable for restless animals.

The agglutination and complement fixation tests were made in addition to the above but were always conducted before the conjunctival reaction. Autopsies made of the 13 animals agreed with the findings of the mallein test in all cases, while the agglutination and complement fixation tests were negative in two cases where the animals were positively glandered. The conjunctival test is deemed a good one providing it is carefully conducted and the results obtained properly interpreted.

Observations in regard to the influence of mallein on the results of other diagnostic methods with sound horses, R. REINHARDT (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), No. 6, pp. 295-306).—For this work mallein siccum (Foth) was used in the ratio of 0.03:5 cc. in 0.5 per cent carbolic acid solution. The solution was used for both the conjunctival and cutaneous tests, although for the latter mallein brute (Pasteur Institute) and concentrated mallein (Klimmer) were also employed. In addition to the above tests the precipitation, complement fixation, and agglutination tests were compared.

A cutaneous or conjunctival instillation of mallein did not have any influence upon the outcome of a thermomallein reaction nor upon the serologic blood tests. Evidently the amount of antigen taken up by the blood stream as a result of cutaneous or conjunctival introduction is too small to produce appreciable amounts of antibodies. By giving mallein once or twice subcutaneously no effect on a subsequent cutaneous or conjunctival test with mallein was produced.

As a result of giving mallein subcutaneously, in most instances a negative precipitation reaction was obtained, and only in one instance where Foth's mallein was used was a positive reaction noted. In a few instances the complement fixation reaction was positive after mallein was introduced either once or twice subcutaneously. In these cases one horse showed positive 29 days after receiving the antigen for the first time, and 2 other animals after 13 (negative for 151 days), 19, 29, and 42 days (negative 157 days), respectively, after a second injection.

According to the tests complement-fixing bodies may be in the blood of sound horses after 3 days and on an average in from 4 to 9 days. The bodies which result from giving a second injection seem to remain longer than those produced by a single injection. The agglutination value was found to be raised in every instance when mallein was injected. The agglutinins required about 3 days or a little over for their production and the highest value was noted in a horse 8 days after malleinization. The highest average values were obtained between the eighth and nineteenth days. A second injection in some cases increased this value. When a complement fixation test was obtained the agglutination titer was usually high, but in some cases where the agglutination test was high no inhibition of hemolysis was noted.

The transmission of swamp fever in horses, L. D. SWINGLE (*Wyoming Sta. Rpt. 1913, pp. 93-123, figs. 26*).—The author's feeding experiments with urine and blood of infected animals show that it is not an easy matter to infect the horse through the digestive tract, but do not prove that it is impossible to do so. It is pointed out, however, that the amounts of blood and urine used in the experiments and those used by other investigators who claim to have secured infection by such methods are very large as compared with the amount that a horse could possibly obtain under natural conditions. "Therefore, we may conclude that ingestion of blood or urine is not the natural mode of transmission of the disease and especially would fail to explain epidemics."

Healthy horses which associated with sick ones for about 2 years, running together in the same yard, feeding from the same mangers, and drinking from the same trough, no precaution being taken against transmission, did not contract the disease. In addition these animals drank water and ate grain and hay contaminated with urine and blood from various infected horses, but not a single case of infection resulted, except when directly inoculated hypodermically or intravenously with virulent blood.

In studies made of the blood of all the horses afterwards used in the experiments bodies corresponding to the description and figures presented by Mack in the account previously noted (*E. S. R., 27, p. 684*) were found, and in some cases stained with Giemsa's stain rings similar to those described by Mack were detected. The author states that it is almost certain, however, that the rings in his slides are artifacts, there being all gradations between the small rings, which are doubtful when considered by themselves, and large rings that are unquestionably artifacts. These structures are said to have been found both within or on the corpuscles and in the plasma. The author considers it possible that these bodies are a nonpathogenic *Anaplasma* such as is sometimes found in healthy rats, goats, calves, pigs, and marsupials.

The influence of compensated salt mixtures on the development of polyneuritis gallinarum and beri-beri, R. B. GIBSON (*Philippine Jour. Sci., Sect. B, 8 (1913), No. 5, pp. 351-367, pls. 4*).—"The addition of a compensated salt mixture to white rice fed to fowls has not prevented the development of polyneuritis gallinarum. However, the onset of the disease seems to have been slightly protracted, and the degenerative changes in the nerves were less pronounced."

Reliable poultry remedies (*Quincy, Ill., 1913, pp. 95*).—This is a compilation from the writings of several authors, including P. T. Wood and N. W. Sanborn.

RURAL ENGINEERING.

Increasing the duty of water, B. A. ETCHEVERRY (*California Sta. Circ. 114 (1914), pp. 8*).—This circular summarizes available data, and points out that for an average irrigation system the conveyance losses may be fully 30 per cent of the water diverted, while of the amount delivered 25 per cent or more may be lost by deep percolation, 25 per cent by soil evaporation, and 10 per cent by surface run-off; the total of these losses being 76 per cent of the water diverted.

"By adopting means of conservation which have been used successfully in irrigated districts where water is valuable the waste and loss may be so decreased that the water supply will serve two or three times the area served with the irrigation methods now prevailing in many sections." "Where the value of the water will justify it, concrete linings will decrease the conveyance loss to about 5 per cent of the water diverted; the deep percolation loss, where water is used with care, could be very nearly entirely prevented, and would

probably not exceed 10 per cent of the water applied; the evaporation loss, where the crops will permit deep furrow irrigation and cultivation, will probably not exceed 15 per cent of the water applied; the surface run-off loss or waste can be eliminated. The total losses for these conditions will be about 27 per cent."

Flood flows, W. E. FULLER (*Proc. Amer. Soc. Civ. Engin.*, 39 (1913), No. 5, pp. 1011-1064, pls. 5, figs. 6).—The object of this paper is (1) to present a study of the frequency of floods, (2) to show the relation between the catchment area and the magnitude of the flood, and (3) to present formulas and tables to serve as an aid to judgment in estimating the probable maximum flood to be expected on a river.

It is concluded from this study that although flood flows on different rivers vary greatly some of the characteristics of the rivers affect the floods in substantially the same manner throughout the country. The effect of the size of the catchment area on the flood flows throughout the country is much the same and this relation may be represented approximately by the expression, $Q \text{ (Ave.)} = C A^{0.8}$ in which $Q \text{ (Ave.)}$ equals the average yearly flood in cubic feet per second, C equals a coefficient which is constant for the river at the point of observation, and A equals the catchment area of the river in square miles. The relation between the maximum rate of flood flow on a stream in a period of years and the maximum rate of flow for 24 hours during the same period may be represented approximately by the expression $Q \text{ (Max.)} = Q \text{ (1+2A}^{0.3})$, in which $Q \text{ (Max.)}$ equals the maximum rate of discharge of a flood, and Q equals the greatest average rate of flow for 24 consecutive hours during a period of years. On streams throughout the country, "floods which are a certain ratio of the average yearly flood" occur with much the same frequency, and, on the average, the probable maximum flood in a period of years may be represented by the expression, $Q = Q \text{ (Ave.)} (1 + 0.8 \log T)$; "Coefficients may be obtained for streams by utilizing the foregoing relations to discount the effect of the length of period of observation and the size of the catchment area; these coefficients will serve as a gage for the flood-producing capacity of the streams; and the difference in value of these coefficients is caused by the various physical characteristics of the river and its catchment area, such as storage, soil conditions, etc., and by the difference in the prevailing rainfall conditions."

The storage of flood waters for irrigation: A study of the supply available from southern California streams, A. M. STRONG (*Proc. Amer. Soc. Civ. Engin.*, 39 (1913), No. 5, pp. 955-978, figs. 19).—Investigations on the quantity of flood water being wasted in southern California, and on that part of the waste which may be economically diverted and stored for use during an entire irrigation season, are reported.

Run-off records of the San Gabriel River for two seasons show that if it were possible to obtain storage for the excess run-off available for diversion at an expense warranted by its value, it would be possible to double the area now irrigated from the surface flow of the river.

There are said to be many small streams in southern California similar to this river, a large part of whose floods may be economically handled. Under the assumption that storage facilities are economically available, it is concluded that a diversion capacity of 2.25 second-feet per square mile of drainage area will assure sufficient supply for a reservoir storage of 200 acre-feet for each square mile, irrigating 40 acres, which at 2 cts. per inch per hour would warrant an expenditure of \$13,250 per square mile of drainage area. Similarly, there would be available for increasing the underground storage a supply sufficient to irrigate 45 acres.

Irrigation pocket book, or facts, figures, and formulas for irrigation engineers, compiled by R. B. BUCKLEY (*London, New York, Calcutta, and Bombay, 1913, 2. ed., pp. 483, pl. 1, figs. 80*).—This, the second edition of this pocket book, contains about 60 pages of "facts, figures, and formulas" concerning irrigation engineering which did not appear in the first edition (E. S. R., 29, p. 289).

Drainage and irrigation: Method and cost of manufacturing sand cement with results of tests of the modified cement, L. E. SALE (*Engin. and Contract., 40 (1913), No. 23, pp. 623-628, figs. 6*).—This article describes the methods of manufacturing sand cement employed by the United States Reclamation Service at the Lahontan Dam and gives the results of tests of the modified cement in regard to sand and cement ingredients, tensile and compression strength, porosity of mortars and concrete, and effect of hot water and alkali.

In the sand or so-called "silt" the elements silica and alumina were found to predominate, while the cement analyses showed a high lime content and also sulphuric anhydrid. It was found that an amount of silt, up to 25 per cent of the volume of the sand used, tends to increase the strength and imperviousness of the concrete, it being unnecessary to wash the sand on this account.

Cement replaced by silt, and the two only mechanically mixed, decreased the strength of the concrete in direct proportion to the increase of silt, and too fine grinding of the blend resulted in a flash set. The ideal product was found to consist of a mixture of 50 per cent silt and 50 per cent Portland cement, ground until an average of S2 per cent passed a No. 200 sieve. Sand cement concrete required more mixing and more water than pure Portland cement concrete, and after being placed in forms cracked and disintegrated unless watered constantly for a period of from one to three weeks, depending on the weather. It was further found that hot water could not be used in mixing. The flour in the silt is thought to combine chemically with certain elements in the cement, thus increasing the strength.

From the alkali test it is concluded that an impervious concrete which will resist alkali action can be made with sand cement without resort to "alkali proof" compounds or waterproofing materials such as soap, alum, etc. It is further concluded that sand cement concrete is essentially a warm weather concrete.

Pressure tests of jointed concrete pipes (*Engin. News, 70 (1913), No. 23, pp. 1126, 1127, fig. 1*).—Tests are reported of the resistive qualities under severe internal pressure conditions of lines of 63, 84, and 48 in. reinforced concrete pipe of 1:1½; 2½ mixture and having special "lock joints". The pipe is cast in 4 ft. lengths and is provided with a bell end and a groove on the inside of the pipe at the joint. In making the final joint the reinforcements of the adjoining pipes are overlapped in the internal groove, and the groove filled up flush with the inside of the pipe by pouring in a cement grout. In addition there is a specially prepared plaster interior cover to the joint.

The 63-in. pipe withstood an internal pressure of 54 to 56 lbs. per square inch and the 84-in. pipe an internal pressure of 65 lbs. per square inch without leakage through pipe or joints. The 48-in. pipe withstood 40 to 55 lbs. internal pressure for 48 hours without leakage. A steady increase of pressure in this pipe up to 90 lbs. per square inch caused sudden failure at that point.

Small cube pavements of Monroe County, [New York], W. G. HARGER (*Engin. Rec., 68 (1913), No. 23, pp. 624-626, figs. 7*).—Service tests and cost data are reported of surfacing country roads with 2-in. blocks of vitrified clay ash, vitrified shale, and concrete.

It was found that the cube form of pavement is flexible under frost action, thus making it suitable as a surfacing on a macadam base. It is stable under traffic and can be successfully held in place with a macadam or gravel shoulder without the formation of a rut. It gives a satisfactory surface in wet and dry weather, and can be laid late in the season, requiring comparatively simple inspection.

Gravel concrete cubes unprotected by a bituminous surface coat were complete failures under medium and heavy traffic, but when protected by such a coat they served satisfactorily under light traffic. Vitrified pipe clay cubes laid on concrete with grouted joints wore well under heavy automobile traffic and medium team traffic.

Local clay ash cubes laid on macadam base with sand joints withstood light traffic. Vitrified shale cubes laid on a macadam base with wide sandy loam joints stood medium traffic, and when laid on a macadam base with close joints filled with sand or clay loam and oiled or tarred they stood heavy traffic.

It is concluded that concrete cubes at the present cost can compete economically in only a few cases with macadam. Vitrified shale cubes can compete economically with brick roads for the lighter travel, and will probably be able to compete economically with bituminous macadam in many localities in the near future.

Regulations for accident prevention in the use of electricity in agriculture, NOETEL (*Mitt. Deut. Landw. Gesell.*, 28 (1913), Nos. 20, pp. 296-298; 21, pp. 310-314).—A set of rules and regulations are given and various protective arrangements described for the prevention of accidents in the use of high tension electrical power in agricultural work.

Fuel and lubricants for internal combustion engines, B. H. ARNOLD (*Gen. Elect. Rev.*, 16 (1913), No. 10, pp. 708-713, figs. 2; *West. Engin.*, 3 (1913), No. 5, pp. 369-373, figs. 2).—A discussion is given of the antecedents of gasoline and naphtha as well as of their use in order to show why the specific gravity indicates very little of the relative suitabilities of various gasolines and naphthas. The subjects taken up in the discussion are petroleum, its occurrence, composition, and refining, the use of gasoline and naphtha in the engine, specifications and purchase, and the possibilities of other liquid fuels including alcohol and benzol. Under the subject of lubrication it is concluded that the practical working test is by far the best and surest means of determining the merits of a lubricating oil.

Hay and grain elevator, GRÄF (*Deut. Landw. Presse*, 40 (1913), No. 89, p. 1062, figs. 2).—A grain and hay elevator, consisting essentially of an endless chain fitted with carriers for hay or sacks of grain which operates in a vertical shaft, is diagrammatically illustrated and described.

Methods of hitching horses, M. RINGELMANN (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 43, pp. 530-532, figs. 4).—Methods and devices for hitching horses in stalls, which permit both vertical and lateral freedom in feeding, resting, and lying down, are illustrated and described.

Water supply, plumbing, and sewage disposal for country homes, R. W. TRULLINGER (*U. S. Dept. Agr. Bul.* 57 (1914), pp. 46, figs. 38).—This bulletin treats in a simple manner of (1) water supplies with reference to their sanitary aspects, (2) pumping, storage, and distribution of water, (3) simple and durable plumbing systems, and (4) the safe and satisfactory disposal of sewage and waste.

In a detailed discussion of the contamination of farm water supplies and dangers resulting therefrom, such supplies are divided into three classes, which in the order of their liability to pollution are surface supplies, shallow underground supplies, and deep underground supplies. The construction and use of cisterns, cistern filters, and of a water still for household use are described and illustrated, as are also types of wells and methods of sinking; and methods of protection for deep and shallow wells and springs. Attention is called to the frequent pollution of both deep and shallow wells from local sources, and it is stated that the safety of water supplies when near sources of possible surface pollution often depends largely on the character and quality of the material from which they are obtained.

The section on pumping, storage, and distribution includes a detailed description of the gravity, pneumatic tank, and autopneumatic systems of water supply, and a discussion of pumping and types of pumps, including hydraulic rams, with hints on installation and operation.

The important points to be considered in the arrangement of a plumbing system are stated as (1) durability of material and construction, and (2) simplicity. A warning is given against the use of lead pipe or lead lined receptacles for drinking water in private systems.

The process of sewage disposal described is partly mechanical and partly bacterial, consisting of (1) preliminary or septic tank treatment, and of (2) application to a natural soil by surface or subsurface distribution or to a specially prepared filter. This section also discusses the design, location, and construction of single and double chamber septic tanks and final disposal systems, including a grease trap and sewage diverting gate.

"The septic tank, although air-tight and supposedly water-tight, should be located as far from the house and the well or spring as convenience and local surroundings will permit, thus reducing the danger of pollution or nuisance in case of leakage or improper operation of the system. . . . Contrary to the usual opinion, small sewage systems require some watching and care. It is well to study the system and watch the action in the entire plant for any signs of clogging or waterlogging." If the sewage is applied continuously to the disposal system and in such quantities that the system is kept saturated, the filter or disposal area is said to become waterlogged and "sewage sick" and ceases to be effective.

Tables of working data accompany the discussion.

Stable ventilation and ventilation of rural dwellings, W. PINKEMEYER (*Landw. Ztschr. Rheinprovinz*, 14 (1913), No. 45, Sup., pp. 8, figs. 8).—The author discusses from the German viewpoint the location and construction of rural dwellings and barns relative to protection from the weather and insects, light and warmth, and proper ventilation. He states that dwellings should face the south, horse barns the east, cattle barns the east or southeast, and hog houses the south and southeast. He takes up roof construction in relation to ventilation and prefers the reinforced concrete to the wooden roof. In addition he discusses the proper size and location of windows and ventilating shafts. Different methods of construction are diagrammatically illustrated.

[Paint tests], E. F. LADD, W. F. WASHBURN, and G. F. EKEY (*North Dakota Sta. Rpt.* 1912, pt. 3, pp. 292-295, 491-564, figs. 52).—Photographs are given of fences painted in 1907 and 1908 with data on the number of knots in and character of the fence lumber and analyses of paints used in 1911. Data of house tests of paints are reported as are also results of inspection of both houses and fences in 1912. No conclusions as to the wearing qualities of the paints are drawn.

[Analyses of paints], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 2 (1913), No. 20, pp. 353-356).—This gives the results of examining the vehicle and pigment used in making up 8 samples of paints.

RURAL ECONOMICS.

Agriculture, 1909 and 1910.—V, General report and analysis (*Thirteenth Census U. S.*, 5 (1910), pp. 927, pls. 57, figs. 112).—This volume contains a general report and analysis of all the data collected by the Thirteenth Census regarding agriculture by States and geographic divisions. The information relates to population, farms, and farm property; number, acreage, and value of farms classified by tenure, mortgage debt, color, and nativity of farmers; number of live stock and of domestic animals sold or slaughtered; live stock

products; value of all crops and principal classes thereof, and acreage and production of all crops; and selected farm expenses and receipts. The farms are also classified by sizes with their acreage and number of live stock. Data also are given showing farms and acreage irrigated; irrigation works; cost of construction, operation, and maintenance; crops irrigated—acreage, production and value; and acreage irrigated and irrigation enterprises by States.

For the principal items data from the previous census are given for comparative purposes. The more important facts are illustrated by diagrams and maps.

Agriculture, 1909 and 1910.—VII, Reports by States, with statistics for counties (Nebraska-Wyoming) (*Thirteenth Census U. S.*, 7 (1910), pp. 1013, figs 61).—This volume completes the report previously noted (*E. S. R.*, 29, p. 88).

Only 27 per cent of tillable land under cultivation (*U. S. Dept. Agr., Weekly News Letter*, 1 (1914), No. 25, pp. 2, 3).—It is estimated that of the 1,900,000,000 acres of land in the United States 1,140,000,000 are capable of cultivation, 361,000,000 acres are nontillable but valuable for pasture and fruit, and 399,000,000 acres are of no agricultural value. According to the census of 1909, only 311,000,000 acres were in crops. It is stated that the extension of the tillable area will be at greater expense for clearing, drainage, irrigation, etc., and that the increased production of the future will be the result of increased yields per acre as well as the extension of the tillable area.

Agriculture in other lands, A. J. PERKINS (*Adelaide, So. Aust.*, 1912, pp. 123, figs. 26).—This pamphlet gives a description of agricultural conditions, utensils, live stock, special crops, and systems of cultivation as noted by the author in his travels through Egypt, Greece, Turkey in Asia, Great Britain, France, Spain, and Tunis.

Agricultural and live stock statistics of Finland (*Statist. Årsbok Finland*, n. ser., 10 (1912), pp. 101–124).—This is the annual report of Finland giving by governments statistics of acreage, production, and consumption of the principal farm crops for 1910, the butter and cheese manufacture and trade for 1907–1910, and the number of domestic animals for 1910. Comparative data are given for Finland as a whole beginning with 1878.

Rural population of Finland (*Statist. Årsbok Finland*, n. ser., 10 (1912), p. 7).—In 1800 the population of the rural communities was 786,055; in 1850, 1,531,419; in 1900, 2,372,949; and in 1910, 2,658,324, forming 94.4, 93.6, 87.5, and 85.3 per cent, respectively, of the total population. Prior to 1904 there was an excess of females but since that date males have predominated.

The production, consumption, and price of wheat, P. LEROY-BEAULIEU (*Econ. Franç.*, 41 (1913), II, Nos. 36, pp. 341–343; 38, pp. 415–417; 40, pp. 484–486).—The author states that although the production of wheat between 1880 and 1910 increased 66 per cent the population increased only 30 per cent. The failure of the wheat production to keep pace with the increase in population in Germany, Belgium, France, Great Britain, Italy, Netherlands, and Switzerland has caused their average annual imports to increase from 71,000,000 to 127,000,000 quintals between 1881–1885 and 1906–1910. He also discusses the wheat situation in the principal exporting countries and the possibilities of increasing their production to meet the future demands.

The economic significance of large and small establishments in agriculture, E. KEUP and R. MUHRER (*Die Volkswirtschaftliche Bedeutung von Gross- und Kleinbetrieb in der Landwirtschaft*. Berlin, 1913, pp. XXI+414).—This report gives in detail the methods employed in studying the effect of intensive agricultural settlement in the eastern part of Prussia, and points out that there has been a marked increase in both cereal and live stock production and in the revenue from crops per acre.

Revision of British land laws (*Breeder's Gaz.*, 65 (1914), No. 4, pp. 163, 164, figs. 6).—This article contains a discussion of the methods that are advocated in reforming the British system of land tenure, some of which are supervision of land transfer, registration of title, protection against damage by game, minimum wages for agricultural laborers, and the erecting of cottages for small holders.

The practical side of local organization in agriculture, J. A. HERR (*Penn. Dept. Agr. Bul.* 233 (1912), pp. 16).—The author describes what he considers the essentials for success in agricultural organization and gives the by-laws of two successful farmers' organizations in Pennsylvania.

Year book of international cooperation, H. MÜLLER (*Year Book Internat. Coop.*, 2 (1912), pp. V+255, pl. 1).—The first part of this volume is devoted to statistics relating to cooperative societies and gives for practically all European countries, Japan, and the United States information concerning the area, population, agricultural workers, trade, number and membership of the various cooperative societies, types and amount of business transacted, and other facts relating to their organization. The development of wholesale cooperation between 1901 and 1910 is also discussed.

In the second part the author discusses the influence of Dr. William King, the first editor of the *Cooperator*, on cooperative organizations in England under the subjects of purpose, nature, economic theory, and principles of cooperative societies, trade unions and their relations to cooperative societies, and the system of competition and cooperation.

The Jewish agricultural and industrial aid society, L. G. ROBINSON (*Jewish Agr. and Indus. Aid Soc. Ann. Rpt.* 1913, pp. 70, fig. 1).—This is the annual report for 1913 and gives the number and amount of loans granted, closed, and outstanding for 1900 to 1913, the mode of operation, and a description of the credit unions, farm labor departments, and cooperative fire insurance among the Jewish farmers.

The organization of land credit in Argentina, P. E. SMETS (*L'Organisation du Crédit Foncier dans la République Argentine*. Antwerp, Belgium, 1911, pp. 85).—The author discusses the agricultural industries, land proprietorship, railroads, mortgage and personal credit, agricultural warrants, rates of interest, and the legislation of the federal and provincial governments regarding land credit, and describes the national mortgage bank and the foreign institutions furnishing land credit in Argentina.

Agricultural cooperation in Germany and in Ireland, T. B. THACKSTON (*Spartanburg, S. C.*, 1913, pp. 71).—The author outlines agricultural cooperation in Germany and Ireland and shows how the methods employed in these countries may be adapted to meet conditions in South Carolina.

Annual report on the working of cooperative societies in the Bombay Presidency including Sind, R. B. EWBANK ET AL. (*Ann. Rpt. Work. Coop. Credit Soc. Bombay Pres.*, 1912-13, pp. 11+57+3, pl. 1).—Included in this report are tabulated statistics giving details for each society as to its location, receipts and disbursements, rate of interest, assets and liabilities, profits and loss, and classification of loans.

Cooperative credit movement in India, H. D. BAKER (*Daily Cons. and Trade Rpts.* [U. S.], 17 (1914), No. 37, pp. 577-584).—The author explains the function of the Government in establishing cooperative societies, discusses their progress in the different parts of British India, and gives a list of documents containing more detailed information.

The granger movement, S. J. BUCK (*Cambridge, Mass., and London*, 1913, pp. 384, figs. 5, pls. 4).—The author describes the economic conditions of agriculture at the time the "granger movement" began, the history of its organization, its influence on railway legislation, its business organization, and social

and educational features. He concludes that this movement had a marked influence in bringing the railroads under governmental control and in determining the scope and plans of various other agricultural organizations. The greater part of the book is devoted to conditions between 1870 and 1880. A very complete bibliography is included.

Rural social centers in Wisconsin, C. J. GALPIN (*Wisconsin Sta. Bul.* 234 (1914), pp. 38, figs. 20).—The author claims that because the land worker is exempt from close contact with people he is handicapped in the development of his social institutions, that large scale acquaintance must become a rural policy and ideal, and that "fundamental mediums of acquaintance must supplement the casual in order that the constructive power of the community may be recognized and organized into effective institutions to reinforce each individual in his life struggle." He describes a number of typical rural social centers in Wisconsin, including a rural school, rural club, rural church, and rural municipal center, and indicates how each is influencing the social life of the community.

AGRICULTURAL EDUCATION.

Signs of progress in 1913 (*Ontario Dept. Ed., Agr. Ed. Bul.* 7 (1913), pp. 19, figs. 9).—This bulletin contains (1) a list of 174 rural and village schools in Ontario that are endeavoring to qualify for grants for agricultural instruction, as compared with 17 schools receiving grants for this work in 1910, 33 in 1911, and 100 in 1912; (2) suggestions to teachers that will help them to judge for themselves as to the quality of their work, (3) a list of the schools that have organized progress clubs among the pupils in their higher classes, and (4) an article on the Regeneration of Rural Schools, by M. D. Moffat, in which he outlines what Ontario is doing in introducing utility subjects into the schools.

The present organization and status of agricultural instruction in Belgium, J. VANDER VAEREN (*Rev. Gén. Agron., n. ser.*, 22 (1913), Nos. 2, pp. 75-85; 3, pp. 122-127; 4, pp. 174-181; 5-6, pp. 228-232; 7-8, pp. 280-284).—The various types of agricultural schools and courses comprised in the system of agricultural education in Belgium are described.

Instruction in rural home economics abroad, P. SCHINDLER (*Ann. Sci. Agron., 4. ser.*, 2 (1913), II, No. 6, pp. 727-742).—An account is given of what has been done in the teaching of domestic science in European countries outside of France.

Community or local extension work by the high school agricultural department, W. G. HUMMEL (*California Sta. Circ.* 109 (1914), pp. 31, figs. 7).—This circular discusses the advantages and opportunities of local extension work in agriculture, which aims to connect school life with the home life of the community, possible arrangements as to time available for the teacher to carry on this work, its financial support, forms of the work, and what various high school agricultural teachers have actually achieved in these lines and their methods. The author finds that this work is no untried theory, and that "properly conducted, it promotes agricultural knowledge, prosperity, and community spirit among farmers; vitalizes and emphasizes the value of school instruction; and, not least important, furnishes a useful avenue through which the agricultural experiment station may both keep in close touch with farm conditions and needs and disseminate the results of its investigations."

To help boys go to school and yet make a good living raising corn and pigs (*Oreg. Countryman*, 6 (1913), No. 3, pp. 145, 146).—A proposed plan for combining corn and pig clubs with crop rotations on a 2-acre tract is described. The basic idea is that under this system the boy will have plenty of time to

go to school and yet can make enough money from his corn and pigs to support himself and pay for his education.

The county farm adviser, B. H. CROCHERON (*California Sta. Circ. 112 (1914), pp. 12*).—This circular contains a brief explanation of the farm adviser movement and of what the farm adviser is, does, and costs, followed by a copy of the constitution and by-laws for the Humboldt County Farm Bureau as an example of a permanent form of organization, and by a description of a day spent with a farm adviser.

Announcement of correspondence courses in agriculture, W. G. HUMMEL (*California Sta. Circ. 113 (1914), pp. 12*).—Announcement is made of 32 courses intended for farmers, each dealing with a special type of farming, with a brief description of each.

Rural education conferences, 1913 (*Ontario Dept. Ed., Agr. Ed. Bul. 9 (1913), pp. 52, figs. 14*).—This bulletin comprises the addresses on rural education given at the Ontario Educational Association, Toronto, March 26 to 28, and abstracts of the addresses given at the Inspectors' Short Course and Rural Education Conference at the Ontario Agricultural College August 4 to 8.

Addresses given at the rural life conference, Middlebury College, compiled by R. McFARLAND (*Middlebury, Vt., 1913, pp. 48*).—This report contains addresses concerning various phases of rural life in Vermont and gives an extensive list of books relating to rural life and rural activities.

Agriculture in outline for the use of teachers and pupils in schools of all grades, L. O. HAYNES (*Smoot, W. Va. [1913], pp. 87*).—This book is the result of several years' experience in teaching agriculture, especially in summer normal schools. It is intended to be a guide to the teacher in assigning lessons to the student and preparing the lesson assigned, and to save time in reviewing for an examination.

A text-book of sanitary and applied chemistry or the chemistry of water, air, and food, E. H. S. BAILEY (*New York and London, 1913, 3. ed., rev., pp. XX+345*).—A revised edition of an earlier publication (E. S. R., 18, p. 711) in which statistical matter has been brought up to date.

Course in experimental plant physiology (*Philippine Agr. and Forester, 2 (1912), No. 1-3, pp. 35-46*).—A description is given of the course in experimental plant physiology in the Philippine agricultural college. The course in agriculture in this college has its foundation in plant physiology. An outline and directions for experiments are given.

Soils and crops, T. F. HUNT and C. W. BURKETT (*New York, London, 1913, pp. XIII+541, pl. 1, figs. 463*).—This book has been prepared to aid the teacher in presenting the subject matter to pupils between the ages of 14 and 18. Each lesson contains a note to the teacher and 15 paragraphs in which are developed the ideas, or set of ideas, set forth in the lesson. The authors have endeavored to lead the pupil from the simple and known to the unknown and complex, and to have conclusions follow logically from the statements made. In addition to the recitations matter has been provided for laboratory or practical tests, including many experiments and suggestions as to how to conduct them. No collateral reading is suggested for pupils, as the authors believe they have included in the book as much subject matter as can be covered wisely in 16 weeks by pupils of high school age.

Nature, effects, and maintenance of humus in the soil, E. O. FIPPIN (*Cornell Reading Courses, 3 (1913), No. 50, pp. 28, figs. 18*).—This is a popular discussion of the subject of humus in the soil and contains, among other things, diagrams representing the means by which the supply of humus is maintained in the soil, the sources of organic matter, the processes by which it is changed to humus, the proportion of humus in soil materials, and the final product of

the decay of organic matter and humus. A suggested list of books for use in advanced reading on the subject is given, together with a discussion which contains questions on important points.

Laboratory manual of cereals and forage crops, G. LIVINGSTON and M. YODER (*Columbus, Ohio, 1913, pp. 90*).—Almost all of the exercises contained in this manual have been given in the past two years as laboratory exercises in connection with the regular cereal and forage crop course at the Ohio State University. More than one laboratory period of 2 hours per week will be required to complete all of the exercises.

Our domestic birds, J. H. ROBINSON (*Boston, New York, Chicago, and London [1913], pp. X+317, pl. 1, figs. 236*).—The object of this elementary textbook is to tell in plain language the things that every one ought to know about poultry, pigeons, and cage birds.

Nature collections for schools (*Ontario Dept. Ed., Agr. Ed. Bul. 8 (1913), pp. 23, figs. 9*).—This bulletin is intended as a guide to teachers and pupils in making nature study and agricultural notebooks; plant, insect, historical, and miscellaneous collections; a school bulletin board and museum cabinets; and conducting school fairs and children's competitions.

Boys' and girls' club and contest leaflet, C. D. STEINER (*Agr. Ed. [Kans. Agr. Col.], 5 (1913), No. 16, pp. 4*).—This leaflet deals with the family garden and the flower garden and contains information concerning their preparation and care.

Civic days (*Raleigh, N. C.: State Supt. Pub. Instr., 1913, pp. 46, figs. 9*).—This is a compilation of material for use in celebrating Arbor and Good Roads Days in the North Carolina public schools.

MISCELLANEOUS.

Twenty-fifth Annual Report of Louisiana Stations, 1912 (*Louisiana Stas. Rpt. 1912, pp. 32*).—This contains the organization list, a report of the director on the work of each of the stations, a list of the publications issued during 1912, and a financial statement as to the federal funds for the fiscal year ended June 30, 1912, and as to the state funds for the fiscal year ended November 30, 1912. The report of the department of entomology is abstracted on page 655 of this issue.

Twenty-fifth Annual Report of Maryland Station, 1912 (*Maryland Sta. Rpt. 1912, pp. XVIII+341, figs. 63*).—This contains the organization list; a report by the director on the organization, work, and publications of the station; a financial statement for the fiscal year ended June 30, 1912; and reprints of Bulletins 155-167, previously noted.

Twenty-sixth Annual Report of Michigan Station, 1913 (*Michigan Sta. Rpt. 1913, pp. 143-700, figs. 107*).—This contains reports of the director and heads of departments on the work of the station during the year, the experimental features of which are for the most part abstracted elsewhere in this issue; a financial statement for the fiscal year ended June 30, 1913; and reprints of Bulletins 268-271, Special Bulletins 59-61, Technical Bulletins 12-17, and Circulars 18-20, all of which have been previously noted.

Twenty-third Annual Report of North Dakota Station, 1912 (*North Dakota Sta. Rpt. 1912, pts. 1, pp. 35; 2, pp. 288, figs. 2; 3, pp. 289-569, figs. 63*).—Part 1 of this report contains the organization list, reports of the director and heads of departments, and a financial statement for the fiscal year ended June 30, 1912. An article on Sugar Beets in North Dakota is abstracted on page 638 of this issue.

Parts 2 and 3 constitute the report of the state food commissioner. Part 2 deals with food and sanitation and is abstracted on page 665 of this issue.

Part 3 deals with waters, wheats, paints, oils, and farm products, and includes in addition to articles relating thereto and abstracted elsewhere in this issue, analyses of a fertilizer, Paris green, a so-called quack-grass destroyer, sugar beets, and lignite coal.

Annual Report of South Dakota Station, 1912 (*South Dakota Sta. Rpt. 1912*, pp. 37).—This contains a report by the director on the organization, work, and publications of the station, a list of exchanges, a financial statement for the fiscal year ended June 30, 1912, and departmental reports, a portion of that of the horticulturist being abstracted on page 640 of this issue.

Twenty-third Annual Report of Wyoming Station, 1913 (*Wyoming Sta. Rpt. 1913*, pp. 135, figs. 17).—This contains the organization list; a financial statement for the fiscal year ended June 30, 1913; reports of the director and heads of departments; meteorological observations noted on page 619 of this issue; an article entitled *Analyses of Some Wyoming Larkspurs. I*, by S. K. Loy, F. W. Heyl, and F. E. Hepner, previously noted from another source (*E. S. R.*, 30, p. 577); an article entitled *Some Constituents of the Leaves of *Zygadenus intermedius**, III, by F. W. Heyl and F. E. Hepner, previously noted from another source (*E. S. R.*, 30, p. 412); an article on *The Transmission of Swamp Fever in Horses*, abstracted on page 687 of this issue; and reprints of the following press bulletins: Pasture crop for pigs, preparation of lands for first crops, treatment of loose and stinking smut, the formaldehyde treatment for grain and potatoes, importance of proper seed, hay and root crops for the dry farmer, the extermination of prairie dogs and gophers, and state and county fairs.

Station publications, R. J. H. DeLoach (*Georgia Sta. Circ. 69 (1913)*, pp. 8).—This circular explains the functions of an experiment station and presents lists of the bulletins of the Georgia Station to December, 1912, and the press bulletins or circulars to August, 1913.

Dr. K. W. Van Gorkom's East Indian cultivated plants, revised and edited by H. C. PRINSEN GEERLIGS (*Dr. K. W. Van Gorkom's Oost-Indische Cultures. Amsterdam, 1913*, vols. 1, pp. VIII+399, figs. 92; 2, pp. VIII+911, figs. 292; 3, pp. VIII+874+XXVIII, figs. 213).—The revision of this work is a comprehensive treatise in 3 parts, as follows:

Part 1, *The Climate in the Dutch East Indies*, by J. P. van der Stok (pp. 1-31); *The Soil*, by D. J. Hissink (pp. 33-116); *Manures*, by A. Van Bijlert (pp. 117-163); *Growth, Respiration, and Nutrition of Plants, and Propagation, Heredity, and Hybridization*, by F. A. F. C. Went (pp. 165-237, 239-312); *Plant Diseases and their Dissemination*, by J. Westerdijk (pp. 313-399). Part 2, *Rice*, by J. J. Paerels (pp. 1-64); *Sugar Cane*, by H. C. Prinsen Geerligs (pp. 65-163); *Oils and Waxes*, by J. J. A. Wijs (pp. 165-254); *Tea*, by A. W. Nanninga (pp. 255-353); *Cacao and Cola*, by F. W. T. Hunger (pp. 355-458, 459-502); *Tobacco*, by A. van Bijlert (pp. 503-627); *Coffee* (pp. 629-758); *Spices*, by H. J. Wigman (pp. 759-883); *Ethereal Oils*, by P. van Romburgh (pp. 885-911). Part 3, *Indigo*, by C. J. van Lookeren Champagne (pp. 1-56); *Quinin*, by P. van Leersum (pp. 57-176); *Wood*, by A. H. Berkhout (pp. 177-242); *Secondary Crops* (maize, millet, grasses, soy beans, and beans) and *Turnips and Other Root Crops*, by J. J. Paerels (pp. 243-291, 293-338); *Rubber and Gutta Percha*, by P. van Romburgh (pp. 339-418); *Fiber Crops*, by J. Dekker (pp. 419-554); *Sago*, by J. J. Paerels (pp. 555-580); *Fruits and Vegetables*, by H. J. Wigman (pp. 581-658, 659-698); and *Tanning Materials and Dyes and Forestry*, by H. H. Zeijlstra (pp. 699-789, 791-874).

Collection of coefficients for the conversion of weights, measures, and moneys into the decimal metric system, compiled by U. Ricci (*Recueil de Coefficients pour la Conversion des Poids, Mesures et Monnaies au Système Métrique Décimal. Rome: Inst. Internat. Agr., 1912*, pp. 63).

NOTES.

California University and Station.—The enrollment in the correspondence courses, established only a few months ago, is now 7,000, of whom 6,000 students are taking courses in agriculture. The largest registration has been in poultry raising.

Richard Laban Adams has been appointed assistant professor of agronomy and assistant agronomist. Carl Spencer Milliken has been appointed assistant superintendent of agricultural extension, with headquarters at Riverside, and J. A. Armstrong assistant in agricultural extension in the college and station.

Georgia Station.—R. F. Crittenden, one of the oldest members of the board of directors, died March 8, and has been succeeded by W. D. Hammack of Coleman. A department of agronomy has been substituted for the department of agriculture created at the establishment of the station.

Idaho University.—W. H. Olin has resigned as director of the extension department to become agricultural commissioner for the Denver and Rio Grande and Western Pacific railways, entering upon his new duties April 1.

Indiana Station.—Chester G. Starr has been appointed assistant in swine production beginning April 15.

Massachusetts College.—The sixth annual farmers' week had an enrollment of over 1,500, considerably exceeding that of any previous year in spite of unfavorable weather conditions. Sections were provided in field crops and farm management, animal husbandry and dairying, poultry husbandry, fruit growing, market gardening, floriculture and forestry, home economics, and community development.

Missouri Station.—The forestry department has started an extensive experiment with 533 fence posts of 27 kinds of wood to test the economy of preservatives. The different treatments include charring, treating with hot carbolineum, and the use of hot creosote by the brush and tank methods.

Montana College and Station.—G. L. Martin, professor of dairying and assistant dairyman at the North Dakota College and Station, has been appointed assistant professor of dairying in the college, beginning May 1 and succeeding Roy C. Jones, who has accepted a position as county agriculturist with headquarters at Tillamook, Oreg. E. J. Quinn, of the office of the Indiana state geologist, has been appointed assistant chemist in the station vice H. H. Morris, resigned. H. B. Bonebright has resigned as assistant agricultural engineer. In the extension service, John C. Taylor and R. A. Blanchard have been appointed county agents for Fallon and Cascade counties respectively, George H. Cook specialist in agronomy, and W. J. Hartman live stock specialist. Joseph G. Morgan has been appointed assistant in the grain laboratory.

Nebraska University and Station.—The extension service has been reorganized as a division of the college of agriculture coordinate with the station. Superintendent C. W. Pugsley has been made director of the extension service. H. C.

Filley, assistant professor of farm management, has been promoted to be professor of farm management in charge of the department which had formerly been under the direction of Professor Pugsley.

H. B. Carpenter, adjunct professor of animal husbandry, died February 7. Professor Carpenter was a 1912 graduate of the University of Missouri. He was subsequently employed as instructor in animal husbandry in the University of Georgia, coming to Nebraska at the beginning of the present college year.

Cornell University.—Cooperative work has been arranged with Alfred and Rochester universities. At Alfred, the work is to be of an extension nature in charge of Prof. C. O. DuBois. That with Rochester University involves investigations of plant diseases among vegetable growers at Irondequoit. An expert will be appointed under the immediate direction of the University of Rochester and have the use of its laboratories. The New York State College of Agriculture will furnish a portion of the equipment, pay field expenses, and publish the results of the work.

George A. Works, assistant professor of agricultural education in the University of Minnesota, has been appointed professor of rural education and head of the department in the college of agriculture. He is expected to take up his duties July 1, and will offer courses in the university summer session.

W. W. Warsaw, a graduate of the Iowa College, has been appointed assistant in soil drainage to carry on demonstration work. R. J. Gilmore, assistant in the farm course, has accepted a position as head of the biology department of Huron College. John H. Comstock, head of the department of entomology and zoology, is to retire at the close of the present college year.

New York State Station.—E. L. Baker, associate chemist in charge of inspection analyses, has resigned to enter commercial work. His resignation became effective April 1, when Arthur W. Clark, assistant chemist, was given charge of the analytical work in the inspection of fertilizers, feeds, insecticides, and fungicides. Clarence D. Parker has been appointed assistant chemist.

Oregon College.—John E. Larson, superintendent of the Farm Improvement Association of Spink County, South Dakota, has been appointed extension agronomist.

Pennsylvania College and Station.—The new horticultural building which is nearing completion will be dedicated during commencement. This building will cost about \$120,000 and is to be thoroughly equipped for the teaching of vegetable gardening, pomology, floriculture, and landscape gardening.

A county farm bureau was organized in Lycoming County, March 13, making the tenth county in which an organization has been effected.

A cattle feeders' convention was held at the college April 3. Farmers were present from all of the districts where this industry is important and showed special interest in a feeding experiment with 60 cattle bought last fall for this specific purpose. A marked increase in interest among Pennsylvania farmers in the breeding and feeding of beef cattle is reported.

Maurice G. Kains, associate editor of the *American Agriculturist*, has been appointed professor of horticulture and horticulturist, the appointment to take effect July 15.

Rhode Island College and Station.—Walter E. Ranger has been elected president of the board of managers. Charles D. Kimball has been succeeded by Zenas W. Bliss, who will also act as vice-president.

Walter C. Irons, a 1913 graduate of the college, has been appointed assistant in field experiments and has entered upon his duties.

Wisconsin University and Station.—C. P. Norgord, associate professor of agronomy and associate agronomist, has also been appointed superintendent of farmers' institutes, vice George A. McKerrow, retired.

Wyoming Station.—C. J. Oviatt, state leader of farm management, resigned to take effect April 20, to accept a commercial position.

International Commission of Agriculture.—At a meeting held in Paris, February 23, this body considered the invitation extended by the Panama-Pacific International Exposition to hold the Eleventh International Congress of Agriculture at San Francisco in 1915. The decision was reached that it was impossible for the commission to organize such a congress at San Francisco, but that it held itself ready to undertake the sending of a European delegation to a congress organized by Americans.

The proposition of organizing agricultural groups in the governing bodies of the various countries into an international body was also discussed. The commission decided that a preferable procedure was the addition to its own membership of representatives of these groups and that it would welcome for consideration such questions as the national sections should deem it advisable to submit to it.

International Phytopathological Conference.—This conference was held in Rome, February 24 to March 5, with 50 delegates representing 35 countries in attendance. An international convention was proposed under which adhering countries would pledge themselves to enact legislation and administrative measures to prevent the dissemination of plant disease within their own borders, and especially to organize an efficient system of nursery inspection. The establishment in each country of one or more institutions for scientific research in plant diseases and the providing of phytopathological certificates for exported nursery stock were also advocated.

Sixth Annual Corn Exposition.—This exposition, which was held at Dallas, Tex., February 10-24, was of much educational significance. An unusually complete exhibit was made by this Department, covering 10,000 square feet of floor space, and including many subjects of agricultural and general educational interest. Nine branches were represented, including the Forest Service, the Weather Bureau, the Agricultural Education Service of this Office, the Office of Public Roads, and the Bureaus of Animal Industry, Plant Industry, Soils, Entomology, and Chemistry. Probably the most extensive portion of this exhibit was that dealing with the making and maintenance of good roads. This included a large number of models showing the various stages and methods of road making, the use of road machinery, and the value and use of different materials in road making.

Some very striking exhibits were also made by about 30 of the agricultural colleges and experiment stations, as well as by other educational institutions. The stations' exhibits, for the most part, dealt especially with some one important phase of their work. Thus, the Illinois Station gave special prominence to its corn breeding, Missouri to seed selection, Nebraska to studies of the amounts of moisture used by plants at different stages of their growth, Louisiana to its accomplishments in working out some of the problems of the sugar industry, Iowa to soil studies, California to orchard fumigation, Colorado to cereal breeding work, Wyoming to wool production, and South Carolina to cotton. Cornell University again exhibited the model for the rural community center.

American Association for the Advancement of Science.—At a recent meeting of the council, Dr. E. W. Allen of this Office was elected secretary of the new Section M, on agriculture. The selection of a sectional committee for the section and also its representative on the council was entrusted to the vice-president, Dr. L. H. Bailey, and the secretary of the section.

EXPERIMENT STATION RECORD.

VOL. XXX.

JUNE, 1914.

No. 8.

Modern sanitation in its various aspects has been neglected in the farm home and in rural communities to a surprising degree. Theoretically, as the Commission on Country Life reported in 1909, "the farm should be the most healthful place in which to live, and there are numberless farmhouses, especially of the farm-owner class, that possess most excellent modern sanitary conveniences. Still it is a fact that there are also numberless other farmhouses, especially of the tenant class, and even numerous rural schoolhouses, that do not have the rudiments of sanitary arrangement. Health conditions in many parts of the open country, therefore, are in urgent need of betterment. There are many questions of nation-wide importance, such as soil, milk, and water pollution; too much visiting in case of contagious diseases; patent medicines, advertising quacks, and intemperance; feeding of offal to animals at local slaughterhouses and general insanitary conditions of those houses not under federal or other rigid sanitary control; in some regions unwholesome and poorly prepared and monotonous diet; lack of recreation; too long hours of work."

This statement is abundantly corroborated by medical and sanitary statistics. Recent reports of the United States Public Health Service indicate the widespread prevalence in rural sections of such diseases as malaria, typhoid fever, and hookworm, which it has been shown are spread almost entirely through insanitary surroundings. Kellerman and Whittaker of this Department, working in cooperation with the Minnesota State Board of Health in collecting minute data upon seventy-nine selected and typical rural water supplies, found that fifty-nine were polluted, and concluded that "both farm and city are suffering from the careless management of rural sanitation."

The situation is the more serious since in general the health of the rural population is less safeguarded by public agencies than is the urban population. The farmer and his family are less closely in touch with the local health authorities, and lack the benefits of

medical inspection of school children and the comprehensive sanitary regulations, the enforcement of which does so much to secure and maintain hygienic conditions in the urban community with a well organized health department. Physicians also are less accessible in the country, are liable to be called at a more advanced stage of sickness, and in some regions medical attendance is relatively more expensive. The necessity is, therefore, the more emphatic for disease prevention.

Another important consideration is the relation of the farm to the city as that of producer to consumer. Not only does a diminished efficiency on the part of the farmers through disease represent an eventual economic loss to the whole nation, but actual infection may spread from country to city through the streams, the milk, the meat, vegetables, and other farm products. Entirely apart from the humanitarian point of view, there are incurred by the nation enormous aggregate losses from insanitary conditions on the farms, and the improvement of these conditions is a nation-wide obligation.

Undoubtedly, one important reason for the apparent apathy has been the lack of an intelligent realization of the inadequacy and menace of the prevailing practices. This is indicated by the experience of the Commission on Country Life. It will be recalled that the questionnaire which the Commission sent out included an inquiry as to whether the sanitary conditions of the farms of the neighborhood were satisfactory. Some correspondents replied in the negative, but the usual response of the more than 100,000 replies was to the effect that they were as good as could be expected, or as conditions would warrant. The hearings of the Commission in the field, however, developed a very different state of affairs. Through leading questions, intelligent farmers and their wives, country physicians, board of health representatives, and others, developed the fact that conditions were far from satisfactory, that little attention was paid to such matters beyond the bare necessities, that there was a quite widespread indifference to the teachings of modern sanitation, and that the barns and dairies were often more adequately provided for than the farm homes.

Fortunately, with the general advance in rural standards of living in recent years there has come about a considerable awakening of interest among farmers and representatives of rural communities along these lines, as well as among the public as a whole. Modern methods of communication and travel have to a great extent brought the rural districts into closer relationship with the towns and cities. The farmer learns of the improved general health and reduction in the death rate resulting from the decrease of the ravages of contagious disease, which has been brought about through the intro-

duction of such preventive measures as a sanitary water supply, proper methods for the disposal of sewage and garbage, and mosquito and fly extermination, and wishes to avail himself of these benefits. This is evidenced by the correspondence and other appeals received by this Department, the Public Health Service, the agricultural colleges and experiment stations, state boards of health, the agricultural press, and many other agencies, for reliable and practical information as to means of improving existing conditions.

The matter has in a measure attracted the attention of scientists and sanitarians, but the scientific contributions to the subject are still relatively fewer and less adequate than could be desired. The Public Health Service has given special attention to the campaign against the malarial mosquito and the house fly, and the devising of sanitary arrangements to prevent soil and water pollution. Among state boards of health which have been active may be mentioned those of Pennsylvania, Virginia, Minnesota, North Carolina, Indiana, Illinois, and Maine. The more strictly sanitary engineering features of the investigations of these boards have included studies of rural water supplies, particularly the shallow well as regards pollution from local sources, soil pollution, sewage and garbage disposal, and swamp drainage. In Pennsylvania, rural tuberculosis has been a special subject of inquiry.

During the last two years, the United States Bureau of Education has made an extended survey of the sanitary condition of rural schools in various States. Other surveys have been made in Connecticut, Vermont, New York, Idaho, Massachusetts, New Jersey, Pennsylvania, and Virginia, and a large amount of valuable data has been accumulated on this phase of the question.

The work of this Department in rural sanitation has for the most part been along broad lines, consisting in part of coöperation with state boards of health in the examination of rural water supplies, general studies of personal hygiene and nutrition, food and milk supplies, and of such diseases as typhoid fever, malaria, and hookworm, safe disposal of sewage, insects affecting man, and the improvement of home conditions. A large share of its work has consisted of issuing miscellaneous information to individual applicants through the agency of correspondence.

The importance of the subject is also becoming recognized by some of the leading universities and agricultural colleges. Harvard University, for instance, has recently announced a course in rural sanitation under its department of sanitary engineering, in which it is proposed to instruct engineers, health officers, and physicians in the design and construction of sanitary rural dwellings, water supply, sewage and waste disposal, dairy sanitation, handling of farm prod-

ucts, and other allied subjects. The rural engineering divisions of the Iowa State College, Cornell University, and the University of Wisconsin are among others which are handling one or more phases of the problem.

From these and other sources there has been accumulated a considerable amount of valuable data. The field is still far from exhausted, however, and there is abundant opportunity for further inquiry, whether conducted from the medical, economic, or engineering points of view. One special need is for additional studies of typical farms and rural communities for the primary purpose of standardizing farm sanitary conditions on the basis of locality, type of farm, and financial status of the farmer. There must be a more intimate knowledge of rural conditions and a better understanding of what remedies are practicable before scientific measures can be most effectively applied. Many farmers are financially unable to install the more expensive systems of heating, plumbing, and the like, and this class usually includes those who are most in need of improvements. The more urgent problem, then, is that of securing for this class of farmers sanitary surroundings at a cost commensurate with their means. These more elementary, but oftentimes nearly as puzzling conditions, merit more attention than they have hitherto received.

But in many instances the first work is to arouse public interest and appreciation, and effect improvements which will be relatively simple and inexpensive. Often a change of attitude grows out of an understanding of these matters, and much may be expected from suggestion and illustration. The desire for improvement and faith in it must precede any very considerable change, as it must in all methods of practice on the farm. It calls, therefore, for propaganda and educational work, and in this the personal contact and appeal are as essential as they are in dealing with the improvement of methods and practices on the farm. Hence, the methods of extension work and demonstration are specially suited to meet its needs, and the relationship of the subject to agriculture and home economics makes it one which will naturally receive attention. The new extension movement seems to furnish the first opportunity for a widespread dissemination of information and a campaign along these lines. And while it will naturally form only an incidental feature of the larger work of agricultural extension, it may well result in an awakening growing out of broader intelligence. Already the Iowa College has organized in its extension division a distinct section on rural sanitation, while other institutions are giving some phases of it attention, either as a part of their extension work in rural engineering or in connection with their demonstrations in home economics.

As an example of the kind of service that may be rendered there may be mentioned the fact that in some States the demonstration agents are supplied with a spray pump and materials for spraying stables and manure piles to keep down the breeding of flies. The demonstrations which they have given have proved instructive in remedying a condition which has too commonly been accepted as inevitable.

In another State, the keeping of a pig under sanitary conditions with the avoidance of objectionable odors and fly breeding has been demonstrated. By the use of a pen with cement floor and proper conditions for cleanliness the keeping of a pig on a small place or in town is made possible, furnishing a means for garbage disposal, and hence a source of revenue. Already the extension service in many States has been led into numerous features in this field. They develop very naturally out of the close contact which demonstration work provides.

It has already been pointed out that the farmer himself, rather than any external agency, must be the main dependence in a campaign of bettering sanitary conditions. Much can be done, however, to open his eyes and subsequently to point out the way. Thus, it is certain that in many a case needed improvements have been delayed because of the supposed heavy outlay. Not always is it realized that the postponement may necessitate not only more of a direct expense for medical treatment, but sometimes an overwhelming secondary loss through inability to cultivate a crop, to tend live stock, or to transact other important business. It should frequently be possible to convince the farmer by actual figures that the cost of relocating a dangerous water supply, of screening the house, or of draining a swamp may be many times less than the ultimate expense incident to an attack of typhoid or malaria in his family. It should also be a comparatively simple matter for the sanitary engineer to present to the farmer designs of more or less elaborate water supply, plumbing, and sewage disposal systems well adapted to farm homes, as is now done for stables, silos, and other farm buildings. Some of these may be practicable only for the well-to-do farmer who is able to consider comfort and convenience even at some initial outlay. For the farmer of average means, however, it is possible to point out direct protective methods against disease which he may apply immediately, such as lining his well, screening windows, destroying fly breeding places and rat harbors, providing for removal of slops, garbage, manure, etc., ventilation, and when circumstances demand it, boiling his drinking water. These measures will yield a considerable measure of benefit and protection, and will constitute a powerful impetus to lead him to adopt some of the more expensive projects when financially able.

Another phase of farm sanitation which is in a measure being cared for by this Department, state boards of health, and some agricultural colleges, is that which has to do with the handling of farm produce, such as milk, butter, and other perishable goods. Legislation, in requiring the inspection of dairy stock and of milk products, etc., protects the consumer in a way, but if the farm dairy is unclean or the water supply polluted, such measures will still fail to produce clean milk and butter. It is obvious that such a farm must be kept in a much better sanitary condition than might be tolerated upon the ordinary farm. This will involve an increasing system of inspection, but to be really effective this must also be for a time largely a campaign of education. This is already recognized in many cities, which have devoted considerable attention to personal instruction and help of dairy producers. What is being done in the dairy line might well be extended to other food products, whose proper care and handling are matters for public concern.

In addition to preventing the spread of communicable diseases, the general problem of rural sanitation also involves the improvement of the general health and well-being of the farmer and his family so that they may be better able to resist not only the communicable diseases, but also the noninfectious or constitutional diseases which are also important factors in the death rates of rural districts. Instruction in personal hygiene is even needed in some cases, especially in the case of school children upon whose minds such information will produce a greater impression and lead to better results than is likely to be the case with older people whose habits of living have become more or less fixed. This phase of the problem is hardly one for the extension worker, but it opens wide another door of opportunity for the rural school, and perhaps for such agencies as the newly organized town and country nursing service of the American Red Cross. Its effective utilization will, of course, involve the adequate training of the teacher and the nurse, and in many parts of the country a radical improvement in the sanitary condition of the school building itself.

In many communities this phase might well constitute the beginning of the campaign for improvement in rural sanitation, and the reconstructed rural school become the starting point of a demonstration to be extended to the individual home through the efforts of the college extension staff. Such a campaign, if successful, would do much to make farm life at once more profitable, more healthful, and more attractive, and by so doing contribute to safeguard the food supply, and therefore the health and the efficiency of the nation.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Chemistry, inorganic and organic, C. L. BLOXAM (*Philadelphia, 1913, 10. rev. ed., pp. XII+878, figs. 313*).—This is the tenth edition of this well-known work, which has been rewritten and revised by A. G. Bloxam and S. J. Lewis.

Biochemical hand lexicon, edited by E. ABERHALDEN (*Biochemisches Handlexicon. Berlin, 1914, vol. 8 (Ergänzungsbd. 1), pp. VI+507*).—In this work, which is the latest volume of the series, the sections included are Carbohydrates, by G. Zemplén (pp. 1–366); Fats and Waxes, by A. Grün (pp. 367–460); Phosphatids, and Protagon and Cerebrosids, by D. Fuchs (pp. 461–472); Sterins, and Biliary Acids, by A. Fodor (pp. 473–500). For earlier volumes, see previous notes (E. S. R., 26, p. 106).

Volatility of lactic acid, E. B. HART and J. J. WILLAMAN (*Jour. Amer. Chem. Soc., 35 (1913), No. 7, pp. 919–923*).—A polemic. See other notes (E. S. R., 28, pp. 109, 609; 29, p. 712). The facts pointed out in the present paper, according to the authors, warrant the following conclusions:

“Lactic acid is but slightly volatile in steam at 100°. The amount that passes over in the distillation of volatile acids from silage is insignificant, being equivalent to not over 3 or 4 cc. tenth-normal alkali in 4 liters of distillate. Lactic acid is not sufficiently volatile to enable one to calculate a Duclaux curve for it, as only about 3 per cent passes over in the 100 cc. It is suggested that the higher results of Dox and Neidig in their experiments on the volatility of lactic acid may be due to carbon dioxide in the water used, or to volatile impurities in the lactic acid.”

Phytic acid in cotton-seed meal and wheat bran, J. B. RATHER (*Jour. Amer. Chem. Soc., 35 (1913), No. 7, pp. 890–895*).—Previously noted from another source (E. S. R., 27, p. 611).

Studies on melanin.—V, A comparison of certain nitrogen ratios in black and in white wool from the same animal, R. A. GORTNER (*Jour. Amer. Chem. Soc., 35 (1913), No. 9, pp. 1262–1268*).—Studies in this connection have been previously noted (E. S. R., 23, p. 778; 27, pp. 468, 671). Acting on the assumption that melano-proteins might be formed by the oxidation of some components of the keratin structure an analysis of black and white wool taken from the same animal was made. This was done with the hope of being able to note a chromogen as a part of normal wool structure or possibly as a foreign secretion in the hair follicle “solely for the purpose of pigment formation and not utilized in the elaboration of the hair structure when there is no oxidase present to cause pigmentation, or when there is an inhibition of pigment formation.”

The chemical group characteristics of the various amino acids were studied by D. D. Van Slyke's method.

"The averages of two analyses agree with each other remarkably well, with the exceptions that the humin nitrogen from the black wool is 3.45 per cent in excess and the amino nitrogen in the filtrate from the bases is 2.5 per cent less than that in the white wool. The excess of humin nitrogen is due to the presence of pigment. There is no necessary relationship between the lack of amino nitrogen in the filtrate from the bases and the excess of humin nitrogen. The nitrogen content of white wool was found to be 16.27 per cent while there is only 15.11 per cent of nitrogen in the black wool."

The low nitrogen percentage of the black wool is thought probably due to the presence of melanin, which has a lower nitrogen content than the keratin structure. The author has shown that the nitrogen of the melanin which appears in the humin fraction can only be a part of the true melanin nitrogen present in the wool. Apparently, hydrolysis with strong acids breaks down the melanin molecule. This observation is in agreement with previous work.

On the composition of tyrosinase from two enzymes, M. W. BEIJERINCK (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1912-13), pt. 2, pp. 932-937).—When tyrosinase acts upon tyrosin a substance is obtained which is commonly called melanin. Its color may be jet black, or it may vary between light brown, pure red, brownish red, sepia, and black. The pigment is very stable, resisting heating with strong alkalis and sulphuric acid. Even when boiled with nitric acid, melanin remains almost unchanged.

Melanin is said to be the pigment present in the hair and hide of the higher animals. The theory is that tyrosin, when acted upon first, yields such products as homogentisic acid, ammonia, and carbon dioxide, and by another oxidation the homogentisic acid is converted into melanin.

In this work melanin formation was studied in a culture obtained by sowing garden soils on agar plates containing a medium composed of agar 2 per cent, tyrosin 0.1 per cent (dissolved in a few drops of sodium carbonate solution), and 0.02 per cent of potassium acid phosphate at 30° C. After 2 or 3 days numerous little colonies were formed which consisted of *Streptothrix* (*Actinomyces*). The common bacteria of the soil do not develop at all or only sparingly on the tyrosin plate and can not under the given conditions compete with the slowly growing *Actinomyces*. In some of the colonies a jet black spot was found, and near the center of the spot the *Actinomyces* was always present.

A more minute observation revealed the fact that the *Actinomyces* always lies under a thin glassy layer of fine rod bacteria. "This layer covers like a crust the jet black columns of *Actinomyces* and prevents them from producing spores, which does take place on that part of the mycelium which develops outside the bacterial cover. If from this layer the bacterium is brought into pure culture, which is easily done on broth-gelatin or broth-agar plates, it proves to be an extremely delicate polar ciliate rodlet, which forms no spores and strongly liquefies gelatin. Streaks of the pure culture on a tyrosin plate produce no melanin at all, and in this respect the bacterium resembles *Actinomyces*."

It is obvious from this that pigment formation results from the symbiosis of these organisms. This was proved by additional experiments. The 2 organisms produce no pigments on peptone or broth-containing media. Several other species of *Actinomyces* produce blue, red, or yellow pigments. "In this case it is not tyrosin but glucose, malates, and nitrates that form the chromogenous food, so that the symbiosis is then evidently associated with other factors than those active in the production of melanin from tyrosin."

Experiments made with the *Actinomyces* and the sodium salts of homogentisic acid gave no pigment, but when the other bacterium was present a brown

pigment was formed. The name suggested for the enzym particularly active is "homogentisinase."

Some experiments with tyrosinase obtained from the potato, beet root, and the latex of *Euphorbia lathyris* are also reported.

Oxidases of the female corn bloom, G. DOBY (*Math. és Term. Tud. Értésítő, Magyar Tud. Akad. [Budapest], 30 (1912), No. 2, pp. 324-339, figs. 2; abs. in Ztschr. Gesam. Getreidew., 4 (1912), No. 5, p. 139; Chem. Abs., 7 (1913), No. 1, p. 106*).—The fact that the female inflorescence turns brown after pollination is said to be due to the presence of a peroxidase and an oxygenase. Peroxidase is present only as a reserve enzym, acts in conjunction with the oxygenase, and probably hastens the withering of the organs of the flower when they become superfluous.

The microscopical examination of vegetable products as an adjunct to their chemical analysis, A. L. WINTON (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 18 (1912), Sect. VIIIc, p. 361-366; Amer. Jour. Pharm., 85 (1913), No. 3, p. 132-137*).—This discusses why it is necessary for the food and drug analyst to have a knowledge of botany, especially vegetable histology.

The colorimetric method for determining hydrocyanic acid in plants with special reference to Kafir corn, C. K. FRANCIS and W. B. CONNELL (*Jour. Amer. Chem. Soc., 35 (1913), No. 10, pp. 1624-1628*).—"This work on a method for the determination of hydrocyanic acid was prompted by the need for an accurate knowledge of the amount of hydrocyanic acid, or glucosids containing hydrocyanic acid, that might be found in Kafir corn, milo maize, Johnson grass, and other plants. In work done relative to the amounts of hydrocyanic acid in the saccharin and nonsaccharin sorghums, it appeared that there existed no satisfactory method for the estimation of the small percentages of hydrocyanic acid found in plants. These percentages may vary between 0.0018 and 0.03 per cent."

After reviewing critically the silver nitrate, ferro-ferricyanid, ammonium-alum, lead acetate, mercurous nitrate, and thiocyanate (colorimetric) methods, the last-named with some modifications was decided upon as the most suitable for this purpose. The procedure adopted was as follows:

"In order to render the hydrocyanic acid in the sorghum available, triturate 50 gm. of the finely chopped material with 100 cc. of water; wash into a 1-liter distilling flask with 100 cc. of water. Acidify with 50 cc. of concentrated sulphuric acid and distill about 150 cc. into 50 cc. of a 4 per cent solution of potassium hydroxid. Care should be taken that the end of the condenser dips into the potash solution at all times, or a loss of hydrocyanic acid may result. Make the potash solution to a volume of 250 cc. and use an aliquot equal to one-fifth of the entire solution. To this aliquot add 1 cc. of yellow ammonium sulphid and evaporate to dryness on a water bath. Take up with 10 to 15 cc. hot water and barely acidify with dilute hydrochloric acid. Filter through quantitative filter paper until free sulphur is removed. Add $\frac{1}{2}$ cc. dilute hydrochloric acid and boil 5 minutes. Filter to remove free sulphur; repeat the last operation of boiling and filtering until the solution is absolutely clear. Make up nearly to the mark in a 50-cc. Nessler tube and add 15 drops of 5 per cent ferric chlorid solution. The presence of cyanid in the sample is indicated by a bright cherry-red coloration. If too much acid is present the solution will be lemon-yellow. If alkaline, the iron will be precipitated, but this condition may be corrected by the addition of a few drops of acid. The exact quantity of potassium cyanid present is determined by matching the color with standards in a colorimeter. The standard solution is made to contain 15 gm. of

potassium thiocyanate in a liter of water. This is standardized gravimetrically with silver until 1 cc. equals 14.92 mg. of potassium sulphocyanid, which is equivalent to 10 mg. of potassium cyanid; 50 cc. of this solution is then diluted for use in the Nessler tubes. Thus 1 cc. of the diluted thiocyanate solution is equivalent to 1 mg. of potassium cyanid."

The method was checked up with potassium cyanid 99.6S per cent (Merck). The plants studied were taken from a field in which the poisoning of stock occurred and they contained a maximum amount of cyanogen. These plants were stunted and almost dry from the lack of water.

Assuming that the rumen of a cow has a capacity of 275 liters, which may correspond to a feed content of 200 kg., there would be about 5 gm. of hydrocyanic acid present in the stomach of this animal and this would be sufficient to kill it. "However, no cases are on record of a beef animal eating 200 kg. (nearly 450 lbs.) at one feeding. Besides, the rumen is not emptied at any time but remains in a well-fed animal at about the same weight, the undigestible matter being removed gradually."

Handbook of food analysis, edited by A. BEYTHIEN, C. HARTWICH, and M. KLIMMER (*Handbuch der Nahrungsmitteluntersuchung. Leipzig, 1914, vol. 1, pp. XXIV+1072, figs. 82*).—This volume, by A. Beythien, is the chemical-physical part of a handbook, of which two other volumes are to follow dealing respectively with botanical-microscopical and bacteriological and biological methods. It contains methods for the analysis of meats, soups, milk (including condensed milk), cheese, edible oils and fats, cereals and leguminous seeds, flour, farina, bread, pastry, yeast, vegetables and roots (fresh and conserved), fresh and preserved fruits, jellies, marmalades, fruit juices, fruit sirups, preservatives in fruit juices, honey, beeswax, alcohol-free beverages, sugar and sugar goods, alcoholic beverages (beer, wine, cordials), vinegar, spices, tea and coffee and coffee surrogates, cocoa and chocolate, water, air, miscellaneous materials used in the handling and canning of foods, dyestuffs, paper (cartons, etc.), textile fibers, woven goods, soap, washing compounds, cosmetics, petroleum, candles, matches, poisons, and urine.

In many cases the judgment of the commodity on the basis of the analysis is discussed.

Table of calculated dry substance in milk as determined by the Fleischmann formula, R. PFISTER and W. LEUZE (*Milchw. Zentbl., 42 (1913), Nos. 4, pp. 97-103; 5, pp. 134-138; 6, pp. 169-173; 7, pp. 196-200*).—This table gives the calculated dry substance in quantities of milk varying in specific gravity from 1.019 to 1.04 and in fat content from 0.1 to 6 per cent. The formula $t=1.2 f+2.665 \frac{(100 s-100)}{s}$ is used, in which t represents the dry substance, f the fat content in per cent, and s the specific gravity at 15° C.

The volatile oils, E. GILDEMEISTER and F. HOFFMANN, trans. by E. KREMERS (*London, Bombay, and Calcutta, 1913, vol. 1, 2. ed., pp. XII+677, pls. 2, figs. 75*).—This is a translation of the second revised and enlarged German edition of the first volume of this work, which has been previously noted (*E. S. R.*, 25, p. 113). Its contents are as follows: Historical introduction; production of flower perfumes by extraction, enfleurage, and maceration; principal constituents of volatile oils, natural and artificial perfumes; and the chemical and physical examination of volatile oils.

On Japanese peppermint oil, Y. SHINOSAKI (*Jour. Indus. and Engin. Chem., 5 (1913), No. 8, pp. 658-660*).—A study of peppermint oil produced at the Kitami branch of the agricultural experiment station of Hokkaido and the Odakogetsu Peppermint Oil Trade Association in the Okayama prefecture.

Peppermint oil industry in Japan, Y. SHINOSAKI (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 8, pp. 656-658, figs. 6).—A description, with illustrations, of a method for preparing peppermint oil in Japan. "The Japanese peppermint fields are chiefly located in Hokkaido, Okayama, and Hiroshima prefectures."

The maple sugar industry in Canada, J. B. SPENCER (*Canada Dept. Agr. Bul. 2B* (1913), pp. 64, figs. 32).—This is a well-illustrated bulletin dealing with the history and extent of the maple sugar industry in Canada. It describes the sugar-making plant, its operation, and the marketing of the sirup and by-products. The benefits to be obtained in forming cooperative maple sugar makers' associations and inaugurating maple sugar contests are pointed out.

The glucose and starch industry (*Thirteenth Census U. S.*, 10 (1910), pp. 429-434).—An account of the extent of the starch and glucose industry in 1909.

Manufacture of sugar from wood, A. ZIMMERMANN (*Jour. Roy. Soc. Arts [London]*, 61 (1912), No. 3133, pp. 69-81; *abs. in Chem. Ztg.*, 37 (1913), No. 48, p. 490).—Wood flour when treated in closed retorts with a weak solution of sulphurous acid under a pressure of 6 to 7 atmospheres is decomposed. The resulting products contain about 25 per cent (of the wood used) of sugar and 5 per cent of volatile substances which consist of acetic acid, furfurol, and formaldehyde. The sugar is sold under the name of Bastol and is utilized for the feeding of animals.

The action of ozone upon cellulose.—Its action upon beech wood (lignocellulose), C. DORÉE and MARY CUNNINGHAM (*Jour. Chem. Soc. [London]*, 103 (1913), No. 606, pp. 677-686; *abs. in Chem. Ztg.*, 37 (1913), No. 73, p. 738).—In the presence of moisture ozone acted very rapidly upon woody substances and caused an evolution of carbon dioxid and acid substances. Much of the wood was converted into water-soluble derivatives and after 12 hours there was a loss corresponding to 40 per cent in its weight. The water-soluble substances consisted of acetic, formic, and other reducing acids. Furfurol was also noted.

Utilizing wood waste, J. E. TEEPLE (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 8, pp. 680-685).—This deals with the utilization of wood waste for preparing paper pulp, ethyl alcohol, acetate of lime, wood alcohol, charcoal, turpentine, pine oil, rosin, tar, tar oils, creosote oils, pitch, light oils, wood oils, gas, cattle feeds, acetic acid and acetone, camphor, rosin oils, wood preservatives and paints, disinfectants, sheep dip, perfumes, liniments, and embalming fluid and specialties. The various processes are briefly considered.

Chemistry in relation to the frozen meat industry of New Zealand, A. M. WRIGHT (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 8, pp. 673, 674).—This deals especially with the utilization and shipment of the by-products of the beef industry and the chemical control of this industry. The products considered are frozen meats, oleomargarine, casings, tankage and blood, wool and pelts, preserved meats, and meat extract.

Butchers', packers', and sausage makers' red book (*Chicago, Montreal, and Sydney, 1913*, pp. 129).—This book contains numerous recipes for preparing meat goods such as hams, bacon, sausages, Bologna, etc. The processes are described in detail.

About the occurrence of *Zygosaccharomyces* varieties in wine, MATSUMOTO and KROEMER (*Landw. Jahrb.*, 45 (1913), *Ergänzungs.* 1, pp. 106, 107).—Various kinds of *Zygosaccharomyces* have been noted in other media but rarely in wine. The results of this investigation show that they often occur in wine and under certain conditions of propagation the organism seems to resemble *Debaryomyces globosus*.

Investigations in regard to the occurrence of yeasts belonging to the *Saccharomycodes* in musts which have been oversulphured, KROEMER and HEINRICH (*Landw. Jahrb.*, 45 (1913), *Ergänzungs.* 1, pp. 105, 106).—Unpasteurized must which was hypersulphured was found to contain a species of *Saccharomycodes* instead of the usual wine yeast. The species found did not resemble in all respects *S. ludwigii*.

In regard to the place in the system occupied by *Saccharomyces apiculatus* forms which occur in fruit and grape wines, HEINRICH (*Landw. Jahrb.*, 45 (1913), *Ergänzungs.* 1, pp. 107, 108).—The lemon-shaped yeast occurring in wines could be placed in two classes, i. e., one producing a sausage-shaped cell when grown in must, in some cases being attached to one another and then having a mycelium-like appearance, and the other the typical lemon-shaped form.

The investigations are to be continued.

Report in regard to the activities of the pure yeast culture station, R. LAUE (*Landw. Jahrb.*, 45 (1913), *Ergänzungs.* 1, pp. 168–177).—This deals with the activities of the station in conjunction with wine manufacturers with reference to the fermentation of fruit, berry, and grape musts, the use of pure yeast for secondary fermentations in wine and for the preparation of foaming wines, examination and treatment of diseased wines, and the cultivation and multiplication of pure yeast, and other fermentation organisms.

The work done within the station included comparative fermentation tests with newly isolated pure yeasts and a study of the influence of musts of various sugar contents upon the formation of volatile acids by *Saccharomyces apiculatus*.

The fermentation of cacao, edited by H. H. SMITH (*London*, 1913, pp. LIV+318, figs. 35).—This is a collection of essays submitted by A. Preyer, O. Loew, Fickendey, A. Schulte im Hofe, J. Sack, G. S. Hudson, and L. Nicholls in competition for the prize offered by *Tropical Life*. The fermentation of coffee and tobacco is also considered. The data deal almost entirely with the functions of the fermentation process.

Cacao, J. PEIMBERT Y MANTEROLA (*Estac. Agr. Cent. [Mexico] Bol.* 76 (1913), pp. 26, figs. 2).—This deals with the processes of preparing and fermenting cacao on the island of Saint Thomas in Portuguese northwestern Africa.

Calcium thioarsenate as a spray, S. H. KATZ and P. D. BUCKMINSTER (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 8, pp. 663, 664).—"Calcium thioarsenate is a soluble arsenical compound that is comparatively inexpensive and that has strong fungicidal properties. It can not be used in effective densities for spraying apple trees because of the injury it causes to the foliage. For the spraying of plants less sensitive to arsenic than the apple tree it may be found advantageous."

[Activities of the various state laboratories in Belgium] (*Min. Agr. et Trav. Pub. [Belgium], Off. Rural Raps. et Communs.*, No. 7 (1913), pp. 87–97).—This gives a tabulated statement of the analytical work performed by various laboratories in Belgium. The samples reported upon include fertilizers, feeds and feed cakes, fats, milk, pepper, salt, sugar, wine, and vinegar.

METEOROLOGY—WATER.

Weather forecasting, R. M. DEELEY (*Nature [London]*, 92 (1914), No. 2309, pp. 608, 609).—In this article it is maintained that to be of real service to agriculture correct forecasts should be published for at least seven days in advance, and in view of the importance of such forecasts and of the agricultural interests that would be served a strong plea is made for increased appropriations for the necessary meteorological observations and investigations.

Weather forecasting, W. H. DINES (*Nature* [London], 92 (1914), No. 2311, pp. 659, 660).—The importance and possibility of ultimately securing accurate seasonal forecasts are discussed. The need for this purpose of further study of the causes of cyclones and anticyclones is pointed out.

Bulletin of the Mount Weather Observatory (*U. S. Dept. Agr., Bul. Mount Weather Observ.*, 6 (1914), pts. 3, pp. 61-103, figs. 13; 4, pp. 107-194, figs. 33).—These numbers contain the following articles: No. 3.—The Zodiacal Light (illus.), by M. Hall; Does the Zodiacal Light Come from Any Part of the Earth's Atmosphere? by C. Abbe; and Free Air Data at Mount Weather for April, May, June, 1913 (illus.), by W. R. Blair.

No. 4.—Observations on the Increase of Insolation with Elevation, by H. H. Kimball, and Summary of the Free-Air Data Obtained at Mount Weather for the Five Years, July 1, 1907, to June 30, 1912 (illus.), by W. R. Blair.

Monthly Weather Review (*Mo. Weather Rev.*, 41 (1913), Nos. 11, pp. 1639-1797, pls. 9, figs. 6; 12, pp. 1799-1952, pls. 10).—In addition to the usual climatological summaries, lake levels, weather forecasts and warnings for November and December, 1913, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology, a condensed climatological summary, and climatological tables and charts, these numbers contain the following special papers:

No. 11.—Heavy Snowstorm in Ohio, West Virginia, and Southwestern Pennsylvania; Storm of November 7-10 (on the Great Lakes), by J. H. Armington; Notes on the Rivers of the Sacramento and San Joaquin Valleys, by N. R. Taylor; Notes on Streams and Weather of the Upper San Joaquin Watershed, by W. E. Bonnett; and Variations in Rainfall in California (illus.), by W. G. Reed.

No. 12.—Climatic Summary for the Year 1913 (South Atlantic and East Gulf States), by C. F. von Herrmann; Climatic Summary for the Year 1913 (Lake Region), by H. J. Cox; Notes on the Rivers of the Sacramento and Lower San Joaquin Watersheds during the Month of December, 1913, by N. R. Taylor; Notes on Streams of the Upper San Joaquin Watershed, by W. E. Bonnett; and Notice of Change in the Publication of Climatological Data.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and E. K. DEXTER (*Massachusetts Sta. Met. Buls.* 301, 302, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January and February, 1914. The data are briefly discussed in general notes on the weather of each month.

Evaporation from free water surfaces, LUEDECKE (*Kulturtechniker*, 17 (1914), No. 1, pp. 53-57, figs. 7).—The author briefly discusses the accuracy of measurements of evaporation from free water surfaces and shows the differences in the results obtained by several observers.

A plea for the exact measurement of rainfall, F. FLOWERS (*So. African Jour. Sci.*, 10 (1913), No. 4, pp. 81-86, fig. 1).—It is maintained in this article that the ordinary rain gages do not give the complete information required in regions of torrential rainfall. The use of automatic gages is recommended.

The fight against hail, AUDIFFRED ET AL. (*Bul. Soc. Nat. Agr. France*, 74 (1914), No. 1, pp. 64-91).—This is a review of methods used and results obtained in different districts of France in efforts to afford protection against hail by artificial means, particularly with the so-called "electric niagaras."

Water storage and its advantages, A. C. HOUSTON (*Jour. Path. and Bact.*, 18 (1914), No. 3, pp. 351-364).—The author, by a series of experiments, defends his views regarding the value of storage for reducing the bacterial content of water supplies, as attacked by Coplans, who maintains that in the absence of

disruption by mechanical measures the processes of agglutination and subsequent sedimentation account for the negative bacterial content of water stored in glass vessels at laboratory temperature.

The importance of the quantitative determination of chlorids in the examination and judgment of drinking water, F. MALMÉJAC (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 9, pp. 650-652; *abs. in Rev. Sci. [Paris]*, 52 (1914), I, No. 11, p. 348).—The author maintains that any notable increase in the chlorin content of a drinking water is an indication of contamination. The determination of chlorin, therefore, furnishes a simple means of detecting possible contamination. The indication of contamination afforded by a marked increase of chlorin should, however, be confirmed by complete analysis.

The taste of hard water, A. FRIEDMANN (*Ztschr. Hyg. u. Infektionskrankh.*, 77 (1914), No. 1, pp. 125-142).—Experiments are reported which show that the presence of carbon dioxide, even in very small amounts, imparts a distinct taste to water and that this furnishes a means of rough classification of waters with reference to hardness.

A list of references to articles bearing on this subject is given.

The influence of waste liquors from potassium chlorid factories on the biological purification of water supplies, A. MÜLLER and L. R. FRESSENIUS (*Arb. K. Gsndhtsamt.*, 45 (1913), No. 4, pp. 491-521, fig. 1).—It was found that 3,000 parts of chlorin per million of the raw water did not injure the biological properties of the water for domestic and industrial purposes, but that 6,000 parts per million and over caused a marked injury. Oversalting with waste liquors retarded and, in some cases, prevented putrefaction. The increased specific gravity of the oversalted water hindered sedimentation.

SOILS—FERTILIZERS.

Humus in California soils, R. H. LOUGHRIDGE (*California Sta. Bul.* 242 (1914), pp. 49-92).—This bulletin discusses the nature and value of humus as a soil constituent and presents in detail results of a systematic study of the distribution and composition of humus in each agricultural district of California.

It was found that humus was distributed in California soils to a depth of 12 ft. or more. On account of this wide distribution the percentage is smaller although the total amount is larger than in soils of humid regions. In the first 3 ft., which is considered the soil proper, the California soils contain more humus than soils of humid regions, and the amount in the soils to a depth of 12 ft. is more than double that found in humid soils. The surface soils of California contain on an average 1.28 per cent of humus. The upper 3 ft. of soil proper show an average of 1.06 per cent of humus per foot. The tule swamps have the highest percentage of humus; the deserts the least. The amount of humus is less in close, compact adobe clays than in lighter loam and sandy soils. The soils of the Coast Range valleys in the western part of the State have a higher percentage of humus than those of any other agricultural region of the State, probably because of the greater humidity and denser vegetation of that region.

Attention is called to the fact that the black color of the soil is not always due to a high humus content, since many black soils examined showed a smaller percentage of humus than soils of a gray color, and some contained no humus at all. The humus content was sometimes less in the first foot than in the second as a result of the destruction of organic matter by cultivation and summer fallowing.

The average proportion of nitrogen in the humus of the first foot of the soils was found to be 5.92 per cent; that of each of the upper 3 ft., 5.6 per cent, and somewhat less for the entire 12 ft. It varied from 1 to 20 per cent in individual soil layers.

The organic nitrogen in the soil derived from the humus and dependent upon the amount of the latter varied from almost nothing in the lower depths of the soil to as much as 0.13 per cent in the upper 3 ft., in upland soils. The average for the first foot of the soil was 0.07 per cent; for each of the upper 3 ft. it was 0.05 per cent.

Wide distribution of humus and nitrogen in California soils tends to extend the feeding area of roots of plants and thus increase their power of resistance to drought.

The humus of acid and alkaline peats, J. A. HANLEY (*Jour. Agr. Sci. [England]*, 6 (1914), No. 1, pp. 63-76; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 4, p. 210).—Experiments with a number of acid, neutral, and alkaline peats to determine a safe method for distinguishing chemically between the different classes as regards acidity and alkalinity are reported.

Preliminary tests of 35 peats led to the conclusions (1) that in every soil containing an appreciable quantity of organic matter, part of the humus is soluble in ammonia without previous acid treatment, (2) that soils containing no calcium carbonate give an acid reaction to litmus and vice versa. More detailed studies of the humus of five different typical peats gave the following results: Ammonia apparently dissolved out substances of very nearly the same nitrogen content whether or not the peat was previously treated with acid, and the composition of the humus as regards nitrogen varied only slightly in different peats. Caustic soda gave lower and more significant results than ammonia in all cases, indicating that the soda dissolves "either different compounds or different kinds of the same compounds." An estimation of the nitrogen formed by hydrolysis of proteins and similar compounds in the five peats showed that only the alkaline peats yielded ammonia and this in small amounts.

Tests of the sucrose-inverting powers of the peats showed that this power varied considerably with the different peats and in every case the inversion was greater after acid treatment than before. Further tests of the sucrose-inverting powers of soils led to the conclusion that "the acidity of a soil does not depend on the actual proportion of the acid in the soil . . . [but] on the state of the organic matter in the soil and the proportion of it which is in an acid state. . . . In estimating acidities, then, it is necessary to know not only the proportion of humus in an acid state to the total soil but the proportion of 'humus' as 'humic acid' to 'humus' as 'humates,' and this involves a determination of sugar inverted after treatment with dilute acid."

It is concluded in general that it is never safe to judge the acidity of a soil from the percentage of it directly soluble in alkalis. It appears as though some less general property of acids than solubility in alkalis must be used, in which neutral compounds can not take part, such as inversion of sucrose.

Contribution to the knowledge of typical kinds of peat, H. MINNSEN (*Landw. Jahrb.*, 44 (1913), No. 1-2, pp. 269-330; *abs. in Zentbl. Agr. Chem.*, 42 (1913), No. 12, pp. 796-799).—Studies of numerous samples of peat typical of the high, intermediate, and low moors of Germany as regards their physical and chemical composition, plant and animal origin, heat of combustion, and the determination of quantities of extract using alcohol, ether, and petroleum ether as solvents are reported.

Ash analyses showed a low mineral content of the forest peats and a relatively high mineral content of the muck formations. The lime content of the major-

ity of the high moor peat types was low and that of the low moor types generally high. The lime-magnesia ratio in all the types varied between wide limits and approached unity only in peat very poor in lime. Easily soluble alkalis were present only in very small amounts in any of the types while the iron oxid content was generally high. In peats with a high ash content inorganic sulphur compounds were found while organic sulphur was present in peats having a low ash content. Phosphoric acid was seldom found in noteworthy amounts.

The peat-forming plants investigated were rich in potash and phosphoric acid but had a very variable lime content. Extraction by solvents was best effected when using the peat in fine dust form intermixed with clean sand. Alcohol generally produced the largest amounts of extract and petroleum ether the least, and a so-called pollen muck peat yielded the greatest extract of all the peat types. The bleached moss peat extract increased with the age and decomposition of the peat, being greatest with petroleum ether and least with alcohol as the solvent.

The heat of combustion of the peat types generally decreased with increased ash content and varied according to botanical composition, condition of decomposition, and the content of alcohol soluble matter.

The products of distillation from the different peat types and muck formations depended upon the lime and nitrogen content, as all peats poor in lime and nitrogen gave acid distillates while those rich in lime and nitrogen gave alkaline distillates.

The nature and amount of the fluctuation in nitrate contents of arable soils, E. J. RUSSELL (*Jour. Agr. Sci. [England]*, 6 (1914), No. 1, pp. 18-57, figs. 2; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 4, p. 210).—In extended studies of the nitrate content of arable soils, it was found that in sand, loam, and clay soils this fluctuated regularly, but rarely exceeded 6, 23, and 14 parts per million respectively in the soils except when they were heavily manured, when it sometimes rose to 37 parts. In most of the soils tested the accumulation of nitrate took place most rapidly in late spring or early summer, after which there was usually little if any gain and frequently a loss, except in the hot, dry summer of 1911 when the accumulation continued in some of the soils until September. Losses of nitrate occurred during the winter and were more marked during a wet than during a dry winter.

The fluctuations in nitrate content were more marked on loams than on clays or sands. Clays lost less of their nitrates in winter but accumulated smaller amounts in June and July. Sands lost much of their nitrates in winter and did not accumulate very large amounts in summer. "It appears that the main loss in winter is due to leaching and not to denitrification." A comparison of nitrate contents of cropped and fallow land showed that during late summer and early autumn the fallow land was the richer even after adding the nitrate taken up by the crop. No evidence was found that nitrate was produced in the soil during the time of active crop growth, although nitrate accumulation was taking place on adjacent fallow land. "The rapid rise in nitrate content in spring does not usually set in immediately the warm weather begins; there is a longer or shorter lag. There are indications of greater bacterial activity in early summer than later on." It is concluded "that the factors which determine the accumulation of nitrates in the soil also play a great part in determining the amount of crop production. Thus heavy winter rainfall, which washes out nitrates, tends to reduce crop growth; on the other hand hot dry summers succeeded by dry winters are favorable to nitrate accumulation and therefore to crop growth."

Influence of soils and their water contents on nitrogen transformation, F. MÜNTER and W. P. ROESON (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 15-17, pp. 419-440; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 2, pp. 192-194; *Jour. Chem. Soc. [London]*, 106 (1914), No. 616, I, p. 244).—Investigations are reported on the effect of variable water contents and the addition of organic substances on the transformation of organic and inorganic nitrogenous fertilizers in sand, clay, and loam soils.

Horn meal decomposed more rapidly in dry sand soil than in clay or loam, while with higher water contents there was little difference. Ammonium sulphate transformation and nitrate formation increased with a higher water content in all of the soils. This was more rapid in clay and loam than in sand when wet. With dry soils the reverse was true. Horn meal ammonia disappeared rapidly in all of the soils when wet but was retained longer in dry soil, reaching its maximum amount more rapidly the lighter the soil. The fixed absorption of ammonia salts was greater the heavier the soil. The best nitrate formation from horn meal in all cases occurred in the sand soils and was best in clay and loam, with a medium water content. Ammonium sulphate yielded greater quantities of nitrates and more available plant food than horn meal with two exceptions. In general, the largest nitrate formation occurred between the third and sixth weeks except in wet clay. A high water content caused a marked loss of nitrogen from ammonium sulphate in loam and especially from horn meal in clay and loam.

A liberal addition of sugar so decreased the soluble nitrogen compounds as to cause a deficiency in nitrogen for crops, and caused an increase in nitrate assimilation in all of the soils and a loss of gaseous nitrogen from the sand and loam soils.

Ammonium sulphate decomposed more rapidly in all of the soils when sugar was added, but there was no corresponding increase in nitrate formation.

Effect of CS₂ and toluol upon nitrification, P. L. GAINES (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1914), No. 23-25, pp. 584-595, figs. 2; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 616, I, p. 236).—A previous article on this subject by the same author has already been noted (*E. S. R.*, 30, p. 219). The results of the investigations by the author and other investigators are summarized as follows:

"The detrimental or beneficial effect of toluol or CS₂ upon nitrate accumulation in soils depends (a) upon acting strength of the chemical in question; and (b) upon whether the soil is exposed for the chemical to evaporate.

"Toluol, in strengths approximating 0.1 cc. per 100 gm. soil, exerts no appreciable effect upon nitrification. If the strength exceeds this it may, and usually does, exert a detrimental or even inhibitory effect upon the process for short periods of incubation. However, if the periods of incubation are extended this harmful effect, which may last as long as 150 days, is overcome with strengths up to and including 1 cc. per 100 gm. soil, the strongest tested.

"In strengths of less than approximately 1 cc. per 100 gm. soil CS₂, even for short periods of incubation, does not exert an appreciable effect upon nitrate accumulation. If the strength exceeds approximately 1 cc. per 100 gm. soil, CS₂ may, and usually does, exert a temporary retarding effect which, however, is soon overcome even with as strong a treatment as 5 cc. per 100 gm. soil.

"Samples of soil treated with either chemical in sufficient quantity to entirely inhibit nitrification for a period of 4 to 20 weeks may entirely recover from the effect without reinoculation.

"So far as the results thus far reported from laboratory experimentation can be applied to experimental field practice, it would seem that neither toluol

or CS₂, as previously used, could materially effect nitrate accumulation since practical applications rarely ever exceed approximately 0.1 cc. per 100 gm. soil."

A short bibliography of the subject is given.

The mechanism of denitrification, W. HULME (*Abs. in Proc. Chem. Soc. London*, 29 (1913), No. 420, pp. 307, 308; *Jour. Soc. Chem. Indus.*, 32 (1913), No. 24, p. 1165).—"A series of experiments, conducted with a view to investigate the mechanism of denitrification, showed that this reduction might be divided into two parts, namely, (1) the bacterial reduction, and (2) the enzymatic reduction.

"The fermentation of similar media, one with and the other without potassium nitrate, under anaerobic conditions, showed the gas evolution to consist of nitrogen (98 per cent) and carbon dioxide from the nitrate-containing medium, and of hydrogen (70 per cent) and carbon dioxide from the nitrate-free medium. A medium containing only a very small percentage of nitrate evolved nitrogen and carbon dioxide as long as nitrate and nitrite obtained in the solution, but hydrogen and carbon dioxide appeared as soon as these had disappeared; thus the chemical agent by which the organism reduces the nitrate is nascent hydrogen.

"The media were tested for enzyme action by precipitation with alcohol, drying, dissolving in water, and Chamberland filtration, measured quantities of this solution being added to small quantities of a sterilized 1 per cent solution of potassium nitrate, and the nitrite produced being measured. The results showed a considerable reduction with the 'product' obtained from the nitrate-containing flasks, while that obtained from the nitrate-free flasks was devoid of this reducing power.

"These results were confirmed by a second series of experiments, in which the fermentation took place aerobically. The enzyme solutions in all cases were not affected by boiling."

Equations illustrating the mechanism of denitrification are presented, showing the formation of carbon dioxide by the action of bacteria and of nitrogen by the action of enzymes.

The action of soil bacteria and their relation to condition of the soil and plant growth, H. FISCHER (*Gartenflora*, 63 (1914), No. 2, pp. 33-46).—This article touches briefly on the different activities of soil bacteria in the decomposition and transformation of fertilizing matter into available plant food, taking up particularly the processes of nitrate and carbon dioxide formation, nitrogen losses, nitrogen assimilation, and other related subjects.

Nodule bacteria and preparations for soil inoculation, I. A. MAKINOV (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 6, pp. 341-367, figs. 11).—Examinations and comparative tests were made of several commercial preparations and of crushed nodules for the inoculation of leguminous plants. The commercial preparations were found to be contaminated with other organisms and contained comparatively limited numbers of *Bacillus radicicola*. They were, however, as a rule more effective in promoting growth than the water extracts of the crushed fresh nodules.

Colloidal matter in clay and soils, P. ROHLAND (*Internat. Mitt. Bodenk.*, 3 (1913), No. 6, pp. 487-493).—The nature, properties, and functions of colloids in soils and their importance in agriculture are briefly discussed along the same line as in previous articles (E. S. R., 22, p. 712; 29, p. 817).

The solution and precipitation of iron in the formation of iron pan, C. G. T. MORISON and D. B. SOTHERS (*Jour. Agr. Sci. [England]*, 6 (1914), No. 1, pp. 84-96; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 4, p. 210).—

Investigations on the solution and precipitation of iron in the formation of iron pan or ortstein are reported. The occurrence of iron pan is described and several theories on the subject are briefly reviewed, the authors agreeing with the theory of Müns^a that the formation of iron pan is due to the formation of colloidal humus compounds of iron and aluminum which are precipitated in the soil depths by soluble salts, loss of water, or by change of bases.

Experiments mainly concerned with investigations of the properties of various so-called humates and with attempts to dissolve iron either as ferrous humate or as ferrous bicarbonate under approximately natural conditions led to the following conclusions: (1) Peat is a strong reducing agent but is not capable of reducing ferric oxid to ferrous oxid; (2) the solution obtained by the action of peat on ferric oxid does not contain ferrous humate, which appears to be accompanied by the presence of ferrous ions; (3) peat in the presence of water removes considerable quantities of minerals, especially ferric oxid, aluminum, and calcium oxid, from the soil as colloidal suspensions, which do not seem very sensitive to changes in concentration, although their capacity for suspension is to a certain extent destroyed by evaporation to dryness; (4) in the case of iron the compound formed is probably ferric humate, but possibly an absorption complex of colloidal humus and colloidal ferric hydroxid.

The authors suggest that "the most probable course of events" in the formation of the pan is as follows: Acid substances are produced as the first results of the accumulation of the surface layers of peat, and they remove the more readily attacked soil constituents probably in the state of true solution. At the same time colloidal humates of iron, aluminum, and calcium are formed, probably as gels on account of the comparatively high concentration of the soil solution. As the concentration diminishes during the winter seasons, the gels pass into the sol form which, as the soil dries, follow the receding water table and the colloidal suspensions are deposited by rapid desiccation at a level just above the permanent water table.

A bibliography is appended.

Ferrous iron in soils, C. G. T. MORISON and H. C. DOYNE (*Jour. Agr. Sci. [England]*, 6 (1914), No. 1, pp. 97-101; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 4, p. 210).—Experiments in which 10 gm. of each of four different soils were digested in dilute sulphuric acid and titrated with potassium permanganate, apparently showed large amounts of ferrous iron, which the authors believe are indicated "not because of any large amount really present in the soil, but because the ferric iron which is dissolved by the acid is partially reduced by the organic matter present."

Similar experiments, using clay to which varying quantities of acid peat were added, showed like results. The use of acetic acid as a solvent was found to be unsatisfactory, and it is concluded from these and other experiments that no known method is satisfactory for the determination of ferrous iron in soils, and that the existence of ferrous iron in normal soils to any extent, and of ferric iron in normal soil solution, seems improbable.

Mineral deposits, W. LINDGREN (*New York and London, 1913, pp. XV+883, figs. 257*).—Referring to the fact that "mineral deposits are usually classified and described by the metals or the substances which they contain . . . with little or no effort to separate them into genetic groups" the author states that "this book is the outcome of a desire to place the knowledge of mineral deposits on the broader and more comprehensive basis of a consistent genetic classification. . . . The general plan has been to select a few suitable examples to illustrate each genetic group of deposits."

^a Zentbl. Agr. Chem., 41 (1912), No. 1, pp. 3-10.

Among the agencies involved in the formation of mineral deposits prominent consideration is given to discussion of the flow, composition, and chemical work of underground waters. Among the examples of greatest agricultural interest selected to illustrate the various genetic groups are the nitrate, potash, and phosphate deposits.

Disposal of manure, P. M. HALL (*Amer. Jour. Pub. Health*, 4 (1914), No. 1, pp. 38-42).—This article briefly describes the methods of disposal employed in various cities of the United States and Canada, with special reference to sanitation. It is shown that these methods are generally inefficient from the standpoint of sanitation and wasteful from the standpoint of use of manure for fertilizing purposes.

The production of guano in Chile, G. YUNGE (*Abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 12, pp. 1848-1850).—The total output of guano in Chile from 1844 to 1909 is stated to have been 229,902 tons. The output in 1910, principally from Punta de Lobos, was 12,483 tons, all used in Chile, as export is now prohibited.

Fertilizer economy in Holland, D. P. DE YOUNG (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 34, p. 543).—It is shown that manure and commercial fertilizers are freely used in Holland. Often as much as \$20 to \$30 worth of fertilizer is applied per acre annually. Cattle manure sometimes sells for as much as 25 cts. per wheelbarrow load and is, therefore, carefully saved and used.

Rotation of crops is practiced to some extent but fertilizers are generally deemed sufficient to maintain the fertility of the soil. Deep and thorough tillage is universally practiced. Lime is freely used. In some cases a mixture of 30 cwt. of superphosphate, 20 cwt. of kainit, and 6 cwt. of nitrate of soda is used per acre. Such liberal applications of commercial fertilizers are generally used only where cattle manure is not available.

Production and import of fertilizers in Russia (*Chamber Com. Jour. [London]*, 33 (1914), No. 238, pp. 53, 54).—The statistics of production and import quoted show that there has been a considerable development of the fertilizer industry in Russia in recent years.

The production of superphosphate in 1912 was 135,000 tons. The importation was 206,856 tons, making the total consumption over three times that in 1908. The importation of Thomas slag was 186,246 tons and the production 36,000 tons. The imports of Chilean sodium nitrate was 56,736 tons, the proportion used for fertilizing purposes being unknown but probably one-half. The imports of potash salts amounted to 97,938 tons. There were also small importations of other miscellaneous fertilizer materials.

Recent statistics for the home production of mineral phosphates are not complete, but it is estimated that this was 18,473 tons in 1910.

Commercial fertilizers, 1912 (*Off. Rpt. Sec. Ohio Bd. Agr. on Com. Ferts.*, 1912, pp. 235).—Analyses and valuations of fertilizers licensed for sale in Ohio during the year are reported, with general comments on the results and a series of special popular articles relating to fertilizers as follows: Twelve Important Facts a Farmer Should Know When Purchasing Fertilizers, by H. G. Bell; Important Questions and Answers Relative to the Use of Manures and Fertilizers, The Home-Mixing of Fertilizers, Field Experiments with Fertilizers, Raw Phosphate Rock as a Fertilizer, The Nitrogen of the Fertilizer Sack, What is Lime, and Soil Analysis not a Sufficient Guide to the Use of Fertilizers, by C. E. Thorne; Fertilizing Problems, by A. Vivian; Analysis of Commercial Fertilizers, Use of Fertilizers, and The Phosphoric Acid in Phosphate Slag, by N. W. Lord; and Ammonia or Nitrogen, Filler or Make-Weight Materials, and Potash, by E. E. Somermeier.

Progress in the fixation of nitrogen in Scandinavia (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 2, pp. 163, 164).—This is a brief note on the successful commercial development of the process for oxidizing ammonia to nitric acid by means of the catalytic action of platinum as proposed by Ostwald. Reference is made to works at Odda and Aura, Norway, and to proposed factories in England, Scotland, and Ireland.

Methods of making ammonium sulphate from the sulphur and ammonia in coal gas, M. DESMARETS (*Rev. Gén. Chim.*, 16 (1913), No. 24, pp. 405-411, figs. 3).—The methods of Feld, Burkheiser, and others are described and their industrial value compared.

The organic synthesis of ammonia, O. SERPEK (*Ztschr. Angew. Chem.*, 27 (1914), No. 8, Aufsatzteil, pp. 41-48).—Investigations bearing upon the development of processes for the purpose are reviewed and the industrial possibilities of such processes are discussed.

The industrial synthesis of nitric acid and ammonia, C. MATIGNON (*Chem. Trade Jour.*, 54 (1914), Nos. 1391, pp. 68-70; 1393, pp. 155, 156; 1394, pp. 179, 180).—A detailed description of the various processes utilized for the preparation of the above-named substances from atmospheric nitrogen. The production of cyanamid is also considered.

Effect of soluble humates on nitrogen fixation and plant growth, W. B. BOTTOMLEY (*Rpt. Brit. Assoc. Adv. Sci.*, 1913; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 18, p. 919).—"The insoluble humic acid present in peat is converted into soluble humate by the action of certain aerobic soil bacteria and the treated peat, after sterilization, forms a suitable medium for nitrogen-fixing bacteria; it is inoculated with the latter and either applied directly to the soil or used for the preparation of a culture solution. The prepared peat not only increases the fixation of nitrogen by the soil but also has a favorable effect on plant growth. Considerably increased yields of radishes, lettuce, turnips, and potatoes have been obtained with it."

Ammonium humate as a source of nitrogen for plants, W. B. BOTTOMLEY (*Rpt. Brit. Assoc. Adv. Sci.*, 1913; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 18, p. 920).—"Ammonium humate has been found capable of supplying the nitrogen need of plants if soluble phosphates and potassium salts be present; it promotes the general growth and has a remarkable effect on the root development of plants. It is prepared by extracting bacteria-treated peat (see preceding abstract) with water, precipitating humic acid from the solution by hydrochloric acid, and dissolving the washed precipitate in ammonia solution."

The bacterial treatment of peat, W. B. BOTTOMLEY (*Jour. Roy. Soc. Arts*, 62 (1914), No. 3199, pp. 373-380).—This is a more detailed account of the investigations briefly noted above, with a discussion of the paper in which attention is called particularly to the claim of the author that peat "humated" by chemical means did not show the stimulating effect of the "bacterized" peat; and his suggestion that since the effects noted can not be due to the small amounts of plant food supplied there must be something in the prepared peat, possibly similar to the accessory bodies in foods, "which has the effect of stimulating and promoting growth in an extraordinary manner." The method of preparing the "bacterized" peat is not disclosed.

The solubility of mineral phosphates in citric acid, G. S. ROBERTSON (*Jour. Soc. Chem. Indus.*, 33 (1914), No. 1, pp. 9-11).—A comparison is made of the solubility in 2 per cent citric acid of the phosphoric acid in basic slag, bone meal, Tunisian raw rock phosphate, and calcined Belgian rock phosphate, with the results obtained with these phosphates in field experiments with grass.

The rock phosphates, particularly the calcined Belgian phosphate, were somewhat more effective as fertilizers than the basic slag.

Submitting these phosphates to repeated extractions with 2 per cent citric acid, it was found that the phosphates were completely soluble in the acid if enough acid was used and the time of extraction sufficiently prolonged, although the ordinary treatment with citric acid showed the phosphoric acid of the rock phosphate to be much less available than that of basic slag. The author, therefore, concludes that the citric acid test is worthless as a means of judging the relative fertilizing value of phosphatic fertilizers.

Investigations on the action of certain soil constituents on monocalcium phosphate in sandy soils, A. G. DAVIS (*Amer. Fert.*, 40 (1914), No. 3, pp. 39-47, figs. 2).—To 300-gm. portions of carefully purified beach sand, were separately added 10-gm. portions each of alumina, ferric oxid, ferrous sulphate, kaolin, lime, and tricalcium phosphate, and to each mixture was added 10 cc. of a solution containing 0.0567 gm. of monocalcium phosphate per cubic centimeter. The mixtures were dried in an oven at 100° C. for 15 hours and then extracted with water.

The results show that of the substances tested alumina and calcium oxid showed the greatest fixing power for phosphoric acid, kaolin and tricalcium phosphate being less active in this respect, and ferric oxid least of all. The ferric oxid at first fixed the phosphoric acid to a considerable extent, but after a time appeared to liberate it gradually in soluble form.

The locking up of phosphate fertilizers in Java soils, A. C. DE JONGH (*Internat. Mitt. Bodenk.*, 4 (1914), No. 1, pp. 32-45).—Experiments with soluble and insoluble phosphates on various Java soils are reported, the results in general tending to confirm Hilgard's conclusions that if highly ferruginous soils are fertilized with soluble phosphates "the phosphoric acid is likely to be quickly withdrawn from useful action, so that any excess not promptly taken up by the crop is likely to become inert and useless; . . . that the phosphoric acid tends to combine with the oxids and hydroxids of the trivalent metals, especially with those of iron, the equivalent aluminic compounds showing the same tendency but to a smaller degree, and that this ferric phosphate is for all practical purposes insoluble and inaccessible to the crop."

The results, however, did not confirm Hilgard's conclusion "that on ferruginous soils rather difficultly soluble phosphates should be used, such as bone meal and Thomas slag, which are said to be more slowly if at all acted upon by ferric and aluminic hydrates," and tend to discredit Van Byler's conclusion "that the degree of usefulness of the fertilizer and the relative amount tied up in the soil is materially affected by the phosphate being either in a soluble or in an insoluble state," since the difference in the results obtained with soluble and insoluble phosphates was insignificant.

Notwithstanding the rapid and extensive fixation of soluble phosphates which took place in certain lateritic soils, it is not, in the author's opinion, to be inferred that moderate application of such phosphates "can not produce a beneficent effect on the crop and good economic results."

The general conclusion is that the fixation of phosphate fertilizers in soils is chiefly due to certain colloidal compounds of the soil.

Influence of "crumbing" of superphosphate and Thomas slag on their action as fertilizers, J. MIKULOWSKI-POMORSKI (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 11-12, pp. 1044-1055).—Superphosphate and Thomas slag which had been made "crumby" by the addition of gypsum or agar-agar were compared with the same materials in fine-ground condition in pot experiments with oats.

The crumbly superphosphate (crumbs 2 mm. in diameter with gypsum and larger with agar) was never less effective than the fine-ground, and in certain cases was more effective. Depth of application had more effect than crumbing. On the other hand, crumbing of Thomas slag reduced the effectiveness of the phosphoric acid.

Accessory constituents of phosphatic slag, A. DEMOLON and G. BROUET (*Jour. Agr. Prat., n. ser., 27 (1914), No. 1, pp. 22, 23*).—Analyses are reported showing on the average about 4 to 5 per cent of manganese, a considerable proportion of which was soluble in 2 per cent citric and acetic acids. The magnesia content was variable but on the average about 10 per cent. The free lime varied from 8 to 10 per cent.

It is suggested that the fertilizing effect of slag may be due in part to the manganese and magnesia which are present to a large extent in available form.

A brief note on the phosphate deposits of Egypt, J. BALL (*Survey Dept. Egypt Paper 30 (1913), pp. 6, pl. 1*).—Phosphate deposits occurring in seven different localities in the deserts of Egypt in the sedimentary strata belonging to the uppermost part of the Cretaceous system are briefly described.

Phosphate deposits were discovered in Egypt in 1900, and their exploitation began in 1908. The output in 1912 was 69,958 tons, mainly from the Safâga and Sibaia districts.

Topography and geology of the phosphate district of Safâga, J. BALL (*Survey Dept. Egypt Paper 29 (1913), pp. 19, pls. 4, fig. 1*).—The topography and geology of this district, which contains the phosphate deposits which are at present of most importance commercially in Egypt, are fully described.

"The phosphatic series consists of laminated gray clays with beds of calcium phosphate and chert, lying below the Upper Cretaceous limestones and above the Nubian sandstone. The total thickness of the series is about 45 meters, of which clays occupy about three-fourths. The phosphate beds occur in the upper part of the series. There are three principal beds of phosphate. . . . The beds vary somewhat in thickness and composition from point to point. . . . The highest bed of the series, . . . which has an average thickness of about 1.8 meters and contains in places as much as 60 per cent of tricalcic phosphate, immediately underlies the Cretaceous limestone, which latter is sometimes marly at its base. Then follows about 5 meters of brown chert beds, with thin bands of hard siliceous phosphate and occasionally thin clay partings. Immediately below the chert comes [the second] phosphate bed, with a thickness of about 1.3 meters and 50 to 75 per cent of tricalcic phosphate. This is followed by some 9 meters of gray and brown laminated clays, separating it from [the third] phosphate bed, which averages about 2 meters in thickness and contains 20 to 45 per cent of tricalcic phosphate. Below [this] phosphate bed the gray and brown laminated clays extend down for some 25 meters to the Nubian sandstone.

"In general appearance the phosphate somewhat resembles an earthy looking limestone or calcareous grit. It is a friable rock of a pale brown color with white spots, made up largely of phosphatic grit with a fair sprinkling of broken up fish bones, coprolites, and teeth. Where it is weathered on exposed faces the phosphate is typically of a darker color than on a fresh fracture, and the harder coprolites in it stand out as black spots, giving it a characteristic speckled appearance, which, though difficult to describe, is readily recognized when once seen. . . . It is generally found that the more friable varieties are the richest, yielding over 70 per cent of calcium phosphate. The top of [the second] seam is frequently formed of a hard variety of the rock, called 'hard panel' by the miners, containing only some 50 per cent or so of phosphate; this

comparatively low-grade rock is not worth extraction, and is left in to form the roof of the workings. The specific gravity of the phosphate is about 2.5."

A study of the phosphate industry, PÉTRÉ (*Bul. Écon. Gouv. Gén. Madagascar*, 13 (1913), III, No. 3, pp. 325-328).—Reference is made to deposits in Madagascar containing from 43 to 50 per cent of calcium phosphate. Methods of testing the phosphates are described and the possible industrial and agricultural use of the deposits is discussed.

German Thomas meal for America, R. P. SKINNER (*Daily Cons. and Trade Rpts.* [U. S.], 17 (1914), No. 38, p. 598).—In 1912 the total export was 662,865 metric tons, to the United States 13,726 tons; during the first 10 months of 1913, 585,122 and 6,127 tons, respectively.

The potash works of Upper Alsace (*Separate from Jahresber. Indus. Gesell. Mülhausen*, 1912, pp. 93, pls. 14, figs. 12).—This report contains information regarding the discovery, geology and mineralogy, exploration (including methods and machinery used and data obtained in numerous borings) and exploitation of the deposits, the chemical and physical character of the natural salts and the methods of purifying them, and the use of the potash salts in industry and agriculture.

Proposed substitutes for Stassfurt potash salts, H. G. SÖDERBAUM (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 86 (1913), pp. 21).—A product prepared by fusing leptit with charcoal and iron filings in an electric oven at 1,800° C. was compared with potassium sulphate in pot experiments with barley on moor soil. Its fertilizing efficiency was 78 per cent of that of the sulphate. The fused product contained about 11 per cent of potash, combined with silicic acid. Of this potash the larger part was soluble in 20 per cent and about half in 2 per cent hydrochloric acid.

The fertilizing value of phonolite, P. WAGNER (*Deut. Landw. Presse*, 41 (1914), Nos. 4, pp. 42, 43; 5, pp. 51, 52).—Two forms of this material offered for sale in Germany were tested in a series of pot experiments, the results indicating that phonolite is of little or no value as a fertilizer.

On the composition of giant kelps, A. R. MERZ (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 1, pp. 19, 20).—A number of analyses of samples of the giant kelps of the Pacific coast is reported. These show, generally, a high percentage of potash (as much as 30 per cent in one case). It was found that the ash content was almost invariably larger in the leaves than in the stems of the same plant, and that the nitrogen content was almost invariably larger in the laminae than in the stipe of the same plant.

Liming of soils, L. FORSBERG (*Jordens Kalkning. Malmö, Sweden*, 1913, pp. 29, pls. 9).—This discusses the action of lime in the soil and methods for determining the soil requirements for lime. Experiments in liming cereals and mangels in sandy and clay soils showed a marked increase in yield from the plat to which lime was applied in 3,000 or 6,000 kg. applications either with or without commercial fertilizers in 3 different fields in Sweden, when these soils showed an acid or neutral reaction.

The gypsum and salt of Oklahoma, L. C. SNIDER (*Okla. Geol. Survey Bul.* 11 (1913), pp. VIII+214, pls. 3, figs. 67).—This report contains chapters on the origin, properties, and occurrence in Oklahoma of deposits of gypsum, the manufacture and use of gypsum products, and the salt resources of the State.

Geology of the salt and gypsum deposits of southwestern Virginia, G. W. STROSE (*Va. Geol. Survey Bul.* 8 (1913), pp. 51-73, figs. 5).—The geology of the salt and gypsum deposits occurring in Washington and Smyth counties, Va., and the development of the salt and gypsum industries in this region are discussed.

AGRICULTURAL BOTANY.

Life processes in resting portions of plants, I, H. MÜLLER-THURGAU and O. SCHNEIDER-ORELLI (*Flora, n. ser.*, 1 (1910), No. 3, pp. 309-372, figs. 3).—An account is given in considerable detail of studies carried out regarding the influence of warmth, etherization, wound stimulation, and enzymes on life processes in the potato and lily-of-the-valley as indicated by separation of carbon dioxid, etc. It is held that the suspension of growth during the resting period of plants and the appearance of the buds are not dependent directly on the amount of material present, but that these are affected largely by factors as yet but little known in this connection.

Life processes in resting portions of plants, II, H. MÜLLER-THURGAU and O. SCHNEIDER-ORELLI (*Flora, n. ser.*, 4 (1912), No. 4, pp. 387-446, figs. 6; *abs. in Bot. Centbl.*, 123 (1913), No. 2, p. 22).—The authors, reporting further investigations (see above) made with resting portions of lilac, lily-of-the-valley, horse chestnut, potato, flag, grape, and strawberry plants, state that increase of sugar following warm baths appeared to be not a direct effect thereof, but the result of an intermediate process thereby induced. Cold storage increased, but warm baths decreased the sugar content of the lily-of-the-valley and potato. In these plants warming increased respiration. Increase of reducing sugars also attended the close of the resting period. Wound stimulus was followed by a slight increase of sugar. In general it appears that metabolism is considerably affected by warming, at least toward the end of the resting period, this being apparently due to a stimulative action bringing about an unstable condition of the protoplasm as evidenced by heightened respiration.

Experiments on shortening the vegetative period, B. PATER (*Ztschr. Pflanzenzücht.*, 1 (1913), No. 4, pp. 469-471).—The author reports that of several plants studied which gave some modification of their customary biennial habit in response to controlled conditions (phosphorus manuring, etc.), *Conium maculatum* and *Verbascum phlomoides* were induced to behave as annuals.

Relation of seed size to general development and anatomy of plants, M. DELASSUS (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 25, pp. 1452-1454).—The author reports that the limitation as to general development, and the final disproportion, noted in plants grown from the smaller seeds in case of horse bean, vetch, chick pea, white lupine, squash, and Indian corn, are comparable with the results previously noted as following partial suppression of reserve materials (*E. S. R.*, 30, p. 132).

The influence of temperature on phototropism in seedlings of *Avena sativa*, Miss M. S. DE VRIES (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1913), pt. 2, pp. 1170-1174, figs. 2).—The author states that this preliminary report, giving results of studies on phototropism of seedlings of *A. sativa*, was called forth at this stage by the contribution of Nybergh (*E. S. R.*, 28, p. 630). It is stated that the lack of influence of temperature in phototropic stimulation reported by Nybergh is opposed to results obtained by the present author, who claims to have noted a definite influence and established optimal points for warming periods differing in duration.

On the connection between phyllotaxis and the distribution of the rate of growth in the stem, J. H. VAN BURKOM (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1913), pt. 2, pp. 1015-1020, figs. 3).—This is a statement preliminary to the author's forthcoming thesis regarding periodic measurements made on various plants in the botanical garden at Utrecht.

Along with curves and other data presented, the statement is made that in *Asparagus officinalis*, *Gingko biloba*, *Hedera colchica*, and *Linum usitatissimum* growth increased regularly from below upward to a maximum, decreasing

above this, while *Acer dasycarpum*, *A. platanoides*, *Deutzia scabra*, *Lonicera tatarica*, *Syringa vulgaris*, and *Viburnum veitchi* showed a similar curve of growth rate, except that the zones containing nodes showed less growth than those nearest them. Shaded stems showed not only a somewhat greater rate of growth, but a longer period of growth for the nodes individually in some cases observed.

Relative transpiration in rain-forest and desert plants, F. SHREVE (*Abs. in Science*, n. ser., 39 (1914), No. 998, p. 260).—The author defines relative transpiration as the ratio of the absolute transpiration of a unit area of leaf surface to the concurrent evaporation from a unit area of water. This is believed to give an index of the physiological control of transpiration and of the action of light upon it. The relative transpiration of a number of plants has been studied in Jamaica, representing rain-forest plants, and in Arizona, representing desert conditions.

A comparison of the rates of the relative transpiration in rain-forest and desert plants shows them to be of the same order of magnitude in the two groups. Since the annual evaporation total in Arizona is ten times that in Jamaica, it is said to show that the absolute transpiration per unit in plants of the desert is approximately ten times as great as it is in the rain-forest.

Relation of transpiration of white pine seedlings to evaporation from atmometers, G. P. BURNS (*Abs. in Science*, n. ser., 39 (1914), No. 998, pp. 259, 260).—The author has reported on an attempt made to express the data recorded by meteorological instruments in terms of plant physiology and thus give them a botanical significance. Experiments were conducted in a state forest nursery with white pine seedlings, comparisons being made with black and white atmometers under half shade, no shade, and full shade. Comparing the water loss under the different conditions gave coefficients of transpiration by which the author claims it is possible to calculate the water loss from white pine seedlings from the evaporation from the atmometers.

Plants grown under the three conditions studied showed great variation in structure, in the amount of ash, and in their chemical composition. The amount of water transpired by the no-shade plants was many times that transpired by plants in half and full shade, but the percentage of ash figured on a dry matter basis was less in those plants than in either of the other two sets experimented upon. Half shade was found to reduce the transpiration and evaporation, but the graphs showed that the response of the plants and the atmometers was not identical.

Transpiration of *Silphium laciniatum*, L. A. GIDDINGS (*Abs. in Science*, n. ser., 39 (1914), No. 998, pp. 258, 259).—Experiments carried on in the laboratory and field with *S. laciniatum* are reported. In both cases special attention was given to the effect of increased wind velocity on the rate of transpiration. In the laboratory transpiration was found to increase with wind velocity up to a certain limit, after which it did not increase in proportion as the wind velocities were increased. As a rule in the field experiments transpiration was found to be greatest before evaporation had reached the maximum.

The effect of certain surface films and dusts on the rate of transpiration, B. M. DUGGAR and J. S. COOLEY (*Ann. Missouri Bot. Gard.*, 1 (1914), No. 1, pp. 1-22, pl. 1; *abs. in Science*, n. ser., 39 (1914), No. 998, p. 259).—Attention is called to the commonly observed fact that leaves of plants sprayed repeatedly with Bordeaux mixture may remain green and healthy at the close of the season several weeks after unsprayed leaves free from fungus disease have ripened. There seems to have been no data offered explaining the reason for this extended vegetative period.

A series of experiments was conducted in which standardized castor bean leaves and tomato plants were sprayed with Bordeaux mixture, aluminum mixture, lime, and certain other film-forming liquids and powders. In every case the rate of transpiration was higher in the Bordeaux sprayed plants than in the controls. The important differences observed make it necessary to give weight to increased transpiration in any explanation that is offered concerning the stimulating effect of Bordeaux mixture.

Relation of certain grass-green algae to elementary nitrogen, J. R. SCHRAMM (*Abstr. in Science, n. ser.*, 39 (1914), No. 998, pp. 260, 261).—The author states that the number of species of algae, in which the free nitrogen fixation has been investigated under pure culture conditions, is relatively small, not more than 4 or 5 genera having been so studied.

By a variety of methods 25 species were isolated as pure cultures, 2 of them being blue-green algae, 2 diatoms, and the remainder grass-green algae. Seven species of the latter were tested for nitrogen fixation in the complete absence of combined nitrogen. At the same time the effect of the slightly elevated temperature was determined in a duplicate series of experiments. No fixation of nitrogen was observed in any of the species and, unlike certain fungi, no favorable effect was exercised by the higher temperature.

Metabolism of the nitrogen in *Aspergillus niger*, H. J. WATERMAN (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1913), pt. 2, pp. 1047–1057, fig. 1; *abstr. in Jour. Chem. Soc. [London]*, 104 (1913), No. 610, I, p. 945).—The author summarizes the findings of this study substantially as follows:

The ratio of the nitrogen fixed to the carbon assimilated in *A. niger* lowered with time, becoming constant in the mature mold. The rapidity of the metabolism is subject to great changes, that of nitrogen resembling closely that of carbon as regards factors concerned in their production and rate of change. Metabolism of nitrogen is but little influenced by substitution of rubidium for potassium and is independent of the nitrogen source. No fixation of atmospheric nitrogen was observed.

Metabolism of the phosphorus in *Aspergillus niger*, H. J. WATERMAN (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1913), pt. 2, pp. 1058–1063).—In addition to having shown (see above) that the metabolism of nitrogen in *A. niger* is analogous to that of carbon, the author further claims to have found that phosphorus behaves in much the same manner as do those two elements. It is held, further, that the quantities of the elements present in the mature mold do not correspond to the quantities really active during development, also that the same quantity of an element may be several times active in metabolism, one cell taking up the products given out by another.

Potassium, sulphur, and magnesium in the metabolism of *Aspergillus niger*, H. J. WATERMAN (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1913), pt. 2, pp. 1349–1355).—Referring to the reports above noted, the author states that like carbon, nitrogen, and phosphorus, the sulphur is accumulated in the cell and afterwards partly excreted. In the physiological action of potassium two functions are to be distinguished, one corresponding with that of rubidium, the other with that of manganese. Magnesium differs from the other required elements in that strong concentrations and some time are required to produce any considerable growth therewith. It is thought that magnesium may act by counteracting some as yet unknown noxious factor present. Zinc can replace magnesium in the culture media, but the same is not true of beryllium, lithium, manganese, and calcium. No action by cadmium, strontium, and mercury analogous to that of zinc in this respect has yet become evident. Extremely slight quantities of zinc are sufficient to activate magnesium.

The influence of iron in the development of barley and the nature of its action, J. WOLFF (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 21, pp. 1022-1024).—In experiments briefly noted, neither chromium nor nickel was able to replace the iron constituent in the nutritive medium.

The catalytic action of iron in the development of barley, J. WOLFF (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 25, pp. 1476-1478).—In continuance of the studies above reported, the author found that while the addition of iron in the form of ferrocyanid or citrate increased the weight of the plant it did not increase in the same degree the amount of iron in the plant. The iron is thought, when present in appropriate concentration, to act as a catalyzer.

Influence of the salts common in alkali soils upon the growth of rice plant, V. K. MIYAKE (*Bot. Mag. [Tokyo]*, 28 (1914), No. 325, pp. 1-4).—Continuing work previously noted (*E. S. R.*, 30, p. 630) the author tested barium and strontium for indications of favorable action similar to that of calcium in neutralizing the toxicity of other metallic ions. It was found that the injurious effect of the metallic ions tested (magnesium and sodium in solutions of their chlorids) upon the growth of rice seedlings is perfectly counteracted only by calcium, strontium retarding only in a slight degree their toxic effect, and barium appearing actually depressive in its effect in this connection.

The antitoxic action of chloral hydrate upon copper sulphate for *Pisum sativum*, R. P. HIBBARD (*Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 13-18, pp. 302-308, fig. 1; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 613, I, p. 1284).—During the summer of 1912 the author conducted experiments to learn what relation exists between two poisonous substances when one is a known narcotic. In these experiments copper sulphate and chloral hydrate were used in varying concentrations, and the effect on garden peas, as shown in the length of the roots, was determined.

Observations were made at the end of 24 and 48 hours, and the curves showed that poor growth took place in solutions where the single substances were used except at the lowest dilutions, while a noticeably better growth was obtained where the two substances were combined. The antitoxic action of the combined solutions was especially noticeable where the amounts of the different solutions were nearly equal.

A number of theories are proposed to explain the antagonistic action described above. These involve effects produced within the solution itself, in the plasma membrane, or within the cell, or possibly there may be a combination of all these effects. Another theory proposed to account for the action is that in the particular case studied the action of chloral hydrate in antagonizing copper sulphate might come about through the anticatalytic action of the organic substance.

The influence of etherization on certain enzymatic activities of bulbs and tubers, M. M. MCCOOL (*Abs. in Science, n. ser.*, 39 (1914), No. 998, p. 261).—Experiments were reported on the relative activity of diastases, oxidases, and catalase in etherized and natural bulbs and tubers. The activity in the enzymes in the material from the two sources was found to differ materially. Diastatic action was greater in the etherized tissues and this was also true for the action of oxidases and peroxidases. Catalase activity, however, was found to be diminished by etherization.

A preliminary report on the isolation and identification of the enzymes of *Fucus vesiculosus*, B. M. DUGGAR and A. R. DAVIS (*Abs. in Science, n. ser.*, 39 (1914), No. 998, p. 260).—It is stated that peculiarities in the carbohydrate and nitrogen metabolism of the *Fucaceæ* have made desirable a determination

of the enzym content of the growing tissues. Although employing various methods the authors were unable to find evidence to indicate the presence of any of the commoner carbohydrases except cellulase. The commoner esterases are likewise absent, but amidases are well represented. Urea, especially, is rapidly transformed and urease is apparently widely distributed in the tissues. Oxidases were not detected by any of the methods tested.

Recent cytological studies on the formation of anthocyanin pigments, A. GUILLIERMOND (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 21, pp. 1000-1002).—The author, reporting on his more recent work (*E. S. R.*, 29, p. 827), states that anthocyanin and certain colorless compounds found therewith are always dependent upon mitochondrial activity. It is thought that while these coloring matters in general make their first appearance in the mitochondria as pigments, they may be the result of a gradual transformation of the colorless compounds above mentioned.

Experimental production of anthocyanin identical with that in autumn leaves, R. COMBES (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 21, pp. 1002-1005).—In a brief account given of a microchemical study of *Ampelopsis hederacca*, the author claims to have effected experimentally the alteration of coloring matters found in the green leaf into a substance responding to tests in the same manner as does the anthocyanin of red autumn leaves and therefore held to be identical therewith. The change is held to be connected with a process of reduction and not of oxidation (*E. S. R.*, 23, p. 528).

Transformation of anthocyanin pigment of red autumn leaves into the yellow pigment proper to green leaves of the same plant, R. COMBES (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 25, pp. 1454-1457).—The author claims to have induced experimentally in leaves of ivy the converse of the change noted above in producing the yellow pigment from anthocyanin by a process of oxidation thereof. It is maintained that the above facts require a corresponding change from the views prevalent hitherto regarding the relations of those pigments to oxygen.

Growth stimulation by Roentgen rays of plant and animal tissues, E. SCHWARZ (*Umschau*, 18 (1914), No. 1, pp. 15, 16, figs. 2).—Besides brief notes of some experiments with Roentgen rays on animal tissues, the author describes briefly the effects of the rays on bean seedlings. Exposure for 30 seconds was without marked influence and 300 seconds duration resulted in complete arrest of development, but exposure for about 150 to 200 seconds gave vigorous growth.

Variability in a vegetatively pure line of a hermaphroditic *Mucor*, A. F. BLAKESLEE (*Abs. in Science, n. ser.*, 39 (1914), No. 998, pp. 256, 257).—The author states that separation cultures from a single spore sowing of the *Mucor* gave a small percentage of colonies that differed sharply from the stock form. The variations consisted in absence and increase or decrease of zygospore production as well as peculiarity in color and growth. Some of these variants are considered as only temporary conditions as they tend eventually to revert to the normal type. Others are believed to be more permanent, but have not yet been sufficiently investigated. All tend, at least in part, to reproduce the new characters and some have maintained these for several generations. It is stated that taxonomists would undoubtedly describe as distinct species these forms, which would all be derived from a single source.

On physiological isolation in types of the genus *Xanthium*, C. A. SHULL (*Abs. in Science, n. ser.*, 39 (1914), No. 998, p. 256).—Attention is called to remarkable variations in the burs of what has been considered *X. canadense* grown in this locality. Three distinct types were selected in the fall of 1912 and were grown together under identical conditions for breeding experiments.

These types bred true notwithstanding their close proximity in the field. Differences were noted, but because they bloomed at different times the types seemed to remain distinct, although there was some evidence that occasional hybrids might occur under natural conditions. In view of these variations, the author believes that the genus needs revision based upon experimental investigation.

Segregation of characters in first generation hybrids from stable species of *Oenothera*, G. F. ATKINSON (*Abs. in Science, n. ser.*, 39 (1914), No. 998, p. 256).—Reciprocal crosses have been made of two wild species, *O. nutans* and *O. pycnocarpa*, which have been cultivated through two generations. These two species are said to differ in a number of clearly observable characters and the reciprocal crosses have given rise to hybrids which show segregation of characters in the first generation. A number of the characters are contrast characters that behave as unit characters in segregation into twin and triple first generation hybrids.

Some correlation phenomena in hybrids, TINE TAMMES (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci.*, 15 (1913), pt. 2, pp. 1004-1014).—This report has already been noted from another source (*E. S. R.*, 29, p. 424).

Bud variations in *Solanum*, E. HECKEL and C. VERNE (*Bul. Soc. Nat. Agr. France*, 73 (1913), No. 8, pp. 612-628).—The substance of this contribution has already been noted from another source (*E. S. R.*, 29, p. 829).

Symbiosis and tuberization in potato, J. MAGROU (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 1, pp. 50-53; *abs. in Rev. Sci. [Paris]*, 52 (1914), I, No. 3, p. 93).—Following up the findings and suggestions of Bernard (*E. S. R.*, 27, p. 224), the author made a study of the influence of fungi living in relations of commensalism in potato plants as related to the development thereof. From this, it is claimed, some evidence was secured regarding the alleged importance of fungi to tuber development.

Rejuvenescence of the potato, A. SARTORY, J. GRATIOT and F. THIÉBAUT (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 1, pp. 45-47; *abs. in Rev. Sci. [Paris]*, 52 (1914), I, No. 3, p. 93).—Taking the view that the potato has degenerated in consequence of its long continued asexual reproduction, and regarding with little hope certain efforts at rapid improvement of related wild forms as noted by Heckel and Verne (*E. S. R.*, 29, p. 829), the authors attempted to secure plants breeding persistently after production from the seed by employment of the supposedly stimulating effect exerted on tubers by certain fungi as noted by Bernard (*E. S. R.*, 27, p. 224). The results obtained in 1912 are said to have been encouraging as regards size, vigor, and health. Those of 1913 are claimed to have been still more so, leading to hopes of the complete practical success ultimately of the methods employed.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from April 1 to June 30, 1912 (*U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 31* (1914), pp. 98).—This gives a list, together with economic notes, on miscellaneous importations of seeds and plants received, to the number of about 800, during the period indicated.

FIELD CROPS.

Report of the Mandalay Agricultural Station, 1911-12, E. THOMPSTONE (*Dept. Agr. Burma, Rpt. Mandalay Agr. Sta., 1911-12*, pp. 41+4).—This report gives results of manurial and cultural experiments with rice and variety tests with rice and other crops.

In comparing 240 and 480 lbs. bone meal, 60 lbs. saltpeter, 60 lbs. nitrate of soda, 200 and 400 lbs. cotton cake, and 12,000 lbs. barnyard manure per acre, the

plat receiving barnyard manure produced 1,886 lbs. rice per acre, the largest yield of any single application. The plat receiving barnyard manure with 240 lbs. bone meal gave the largest yield of any combined application, viz, 2,121 lbs. in 1911.

In another series of experiments the use of 12,000 lbs. of barnyard manure was followed by a yield of 2,559 lbs. rice per acre, a larger yield than either rice straw plowed under, ashes from rice straw, or ashes from 12,000 lbs. barnyard manure. A plat receiving burnt rice husks as a fertilizer produced 1,627 lbs. rice, as compared with 885 lbs. without fertilizer. A plat receiving 250 lbs. nitro-lime gave a yield of 1,295 lbs. rice per acre as compared with 1,346 lbs. with an application of 12,000 lbs. of barnyard manure. With a combination of 60 lbs. bone meal and 15 lbs. nitrate of soda per acre rice was produced of higher specific gravity than with any other sort of fertilizer tried, it weighing 53.87 lbs. per standard basket (4 gal.=45 lbs.) as an average of 3 years, 1910-1912.

In an experiment to determine the best distance to transplant rice, 8 by 9 in. was found to give the largest yield, 1,143 lbs. per acre. Of 1, 2, 3, and 4 seedlings in a hill, 2 seedlings gave the best results. In cultivation experiments sprouted rice sown broadcast and harrowed when the plants were 6 in. high gave the best results.

Report on the agricultural station, Orai, Jalaun [India], of the United Provinces of Agra and Oudh, for the years ending June 30, 1912 and 1913 (*Rpt. Agr. Sta. Orai, Jalaun [India], 1912-13, pp. 1-21*).—Some wheat variety tests are reported in which increased yields were obtained by irrigation. Results are also given of variety tests on various soils with cotton, peanuts, millet, pigeon peas, bulrush millet, sesame, gram, and flax, and manurial and tillage experiments as continued from the preceding year.

Crop rotation experiments at Gross-Enzersdorf, A. VON LIEBENBERG DE ZSITTIN (*Mitt. Landw. Lehrkanz, K. K. Hochsch. Bodenkul. Wien, 1 (1912), No. 1, pp. 1-56*).—This article gives results of several series of experiments which were carried on from 1904 to 1910 with spring and winter cereal rotations, and were designed to throw light on the relative value of fallow, green manure, barnyard manure, and commercial fertilizers.

It was found that the addition of 50 kg. of P_2O_5 per hectare (44.5 lbs. per acre) apparently increased the available nitrogen from 28.9 to 29.83 kg., and the available K_2O from 17.1 to 17.26 kg. per hectare in a continuous grain rotation. In one series an increase of 34.5 kg. of dry matter was attributed to each kilogram of a 50-kg. application of P_2O_5 . With an application of 30,000 kg. of barnyard manure, an increase of 11.15 kg. dry matter was obtained per 100 kg. of the manure.

It is noted that 15.82 per cent of an application of 50 kg. of P_2O_5 per hectare was utilized by the crop of cereals. In the case of the barnyard manure the crop utilized 16.3 per cent of the nitrogen, 23.8 per cent of the P_2O_5 , and 13.3 per cent of the K_2O , but when both of the fertilizers were applied together the utilization by the crop was 31.1 per cent nitrogen, 21.9 per cent P_2O_5 , and 27.1 per cent K_2O in a continuous cereal rotation.

By the introduction of fallow every fourth year into the grain rotation, an application of 50 kg. of P_2O_5 seemed to increase the available nitrogen from 28.9 kg. to 33.7 kg. per hectare, and the available K_2O from 16.9 to 21 kg. When an application was made in this series of 50 kg. of P_2O_5 per hectare, 25.8 per cent was utilized by the crop and an increase of 39 kg. of dry matter was obtained per kilogram of P_2O_5 applied. With barnyard manure an increase of 6.96 kg. per hectare was obtained per 100 kg. of the manure, and 24.7 per

cent of the nitrogen, 23.8 per cent of the P_2O_5 , and 20.4 per cent of the K_2O were utilized by the crop.

It is noted that in the rotations without fertilizers, but including the fallow, the annual available plant food was not increased, but that the accumulation due to fallow made possible larger yields for the 3 succeeding years than for the 4-year rotations without the fallow. When fertilizers were applied, however, it was found that the rotation including fallow fell behind in yields. In a series of 6-year rotations of cereals and sugar beets, the introduction of a vetch crop was followed by greater total yields than either fallow or green manure in the rotation. In this last series it was determined that 62.3 per cent of the nitrogen and 47.5 per cent of the P_2O_5 were utilized by the crop with the rotation including the fallow. With the rotation including the green manure it was found that 48.2 per cent of the P_2O_5 and 40 per cent of the nitrogen were utilized, and with the rotation including the vetch crop 61.4 per cent of the P_2O_5 and 62 per cent of the nitrogen. It is noted that barley gave larger yields, and richer in protein, following winter wheat than when following sugar beets.

The shooting of winter rye and winter wheat when spring sown, A. MURINOW (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 4, pp. 238-254, figs. 2).—Experiments conducted in the greenhouse and in the field at the Moscow station showed (1) that spring-sown winter cereals may shoot without a rest period; (2) that the greater the environmental influences, the smaller the number of plants that came to head; and (3) that the influence of a low temperature was to decrease the number of plants that headed, apparently due to checking vegetative growth. As the greenhouse-grown plants were able to shoot without a rest period and the field-grown plants took a rest period, the author concluded that temperature was the factor that governed the rest period in winter cereals.

The influence of spacing on the development of single plants, E. SPERLING (*Fühling's Landw. Zig.*, 62 (1913), No. 14, pp. 487-499).—In general, with wheat, rye, barley, and oats the total weight of plants increased with the increase in spacing, which ranged from 75 sq. cm. to 400 sq. cm. per plant. With rye, barley, and oats the weight on 400 sq. cm. of space was double that on 200 sq. cm. of space. The weight of grain did not increase so rapidly with increased space, and the percentage of grain to straw and chaff decreased. The average single kernel weights of all the cereals, except spring wheat, increased with the increase in space. With horse beans the total weight of plants and the number of beans per pod increased with the increase in spacing, which ranged from 200 to 1,600 sq. cm. The weight of beans increased more rapidly than the weight of straw and chaff. The percentage of beans to straw and chaff was the reverse of that of the cereals, it being the smallest with the smallest space and reaching the maximum at 800 sq. cm.

Plant breeding from the scientific standpoint, R. REGEL (*Trudy Büro Prikl. Bot. (Bul. Angew. Bot.)*, 5 (1912), No. 11, pp. 425-623; *Beilage*, 1912, Nov., pp. 18, pls. 18).—This work constitutes a discussion of the laws of heredity in their relation to the morphological and biological characteristics of plants, with special reference to cereals and to barley in particular. The findings and opinions of the leading investigators are noted in regard to the nonvariability of inherited factors, the general value of Mendel's law of segregation of characteristics, the prediction of inheritance in plant form, the evolution of the organism, systematic (taxonomic) factors, and the general principles of plant breeding.

Selection in pure lines, MRS. C. and A. L. HAGEDOORN (*Amer. Breeders Mag.*, 4 (1913), No. 3, pp. 165-168, fig. 1).—This points to results obtained by Vilmorin

in 50 years of selection in breeding pure lines of wheat without effect in changing the genetic factors. The authors note that when breeders of either plants or animals have obtained changes in the genetic factors they must have used heterozygous individuals for those factors.

Hybridization of cereal species, F. JESLŃKO (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 10 (1913), No. 4, pp. 311-326, figs. 7).—The literature on the crossing of rye and wheat is reviewed briefly. The author then gives the results he obtained during 1909-1912 in attempting to cross-fertilize over 6,000 wheat and rye flowers, this resulting in only 35 hybrid kernels. The methods employed and the results obtained in the hybridization of wheat and rye, and in using the resulting hybrids in further crossbreeding, are explained and discussed.

It is noted that, judging from the small amount of material obtained, the genetic factors seem to segregate in generations of these hybridizations similar to those of variety crosses of cereals.

A study of mountain forage plants, F. BRIOT (*Jahrb. Weidew. u. Futterbaues*, 1 (1913), pp. 114-125).—This gives in tabular form the results of botanical analyses of open and wooded pastures in the central part of France, as studied in 1903 with a view to improvement. These results show that in general half of the growth found either in the open or in the woods was wild plants that could well be replaced with tame grasses before fertilizers could be used at a profit.

Fiber growing in Texas, W. D. HORNADAY (*Amer. Thresherman*, 16 (1913), No. 6, pp. 9, 10, figs. 3).—This article describes a new fiber plant belonging to the Agave family and which has been used as a basis of investigation by H. C. Stiles in the lower Rio Grande Valley territory. It is a plant described as being able to endure low temperatures, decorticating easily, and having a fiber of about 30 in. in length, the most important feature being its hardiness.

Analytical investigations and experiments in the cultivation of *Medicago sativa* in Uruguay, J. SCHRÖDER (*Rev. Inst. Agron. Montevideo*, No. 12 (1913), pp. 47-67).—The author reports mechanical and chemical analyses of alfalfa seed from different countries, and discusses the chemical analysis and feeding value of alfalfa hay found on the markets of Montevideo, the influence of time of harvest on the chemical composition and feeding value of alfalfa hay, and the effect of rain on the composition of hay. In fertilizer experiments the yields of green forage ranged from 51,700 kg. to 62,800 kg. per hectare, the largest yield being obtained with barnyard manure, superphosphate, and potassium sulphate. The yield without fertilizers was 23,000 kg. per hectare. The average composition of alfalfa hay on the Montevideo market was found to be water 10.3, protein 18.1, fat 3.1, nitrogen-free extract 31.6, crude fiber 26.9, and ash 10 per cent.

Berseem (*Trifolium alexandrinum*), M. CALVINO (*Hacienda*, 8 (1913), No. 12, pp. 368-370, figs. 5).—This gives a description and discusses the uses of this plant in Egypt, and rotations in which it is used there. Its cultivation in Italy is also noted. In trials at stations in central Mexico, a July 14 seeding produced as follows: August 27, 29,750 kg.; October 5, 31,000 kg.; November 5, 18,000 kg.; and December 21, 13,850 kg. per hectare. Four varieties, viz, Muscowi, Fachl, Saïda, and Kadrawi are described, and a rotation of maize, wheat, and berseem for Mexico is discussed.

Experiments in electro-culture, GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 6 (1913), No. 1, p. 15).—The results here given with carrots show no noteworthy influence of electricity.

Contributions to the studies of castor beans, L. RIGOTARD (*Agron. Colon.*, 1 (1913), No. 1, pp. 15-21).—This gives descriptions and analyses of numerous

varieties of castor beans from Guinea, Ivory Coast, Upper Senegal and Niger, India, and Egypt. The data and analyses cover the weight of 100 seeds, which ranged from 8 to 22.3 gm.; the dimensions of the seeds, which ranged from 5 by 8 mm. to 7.5 by 11.3 mm.; and the percentages of moisture, oil (which was from 42.2 to 54.6 per cent), protein, lime, phosphoric acid, and potash.

Corn, A. M. TEN EYCK (*Kansas Sta. Bul.* 193 (1913), pp. 429-471, figs. 19).—This bulletin gives some results of testing 226 varieties of corn in the 7 years between 1903-1909, inclusive.

The data show that Kansas-grown seed produces 6.47 bu. more corn on the average per acre each year than the same variety grown from imported seed. It is noted that the high-yielding varieties varied with the year and that high yields are a matter of "breed" or variety, rather than a matter of color or maturing season. Kansas-grown seed usually made a lighter yield of stover than seed from other sources.

A brief history and the principal characteristics of 22 varieties of standard and native varieties of dent corn are given.

Seed corn for Kansas, L. E. CALL (*Kansas Sta. Circ.* 31 (1914), pp. 3).—This circular gives advice to Kansas farmers on buying seed corn locally.

Corn acidity investigation, H. J. BESLEY, G. H. BASTEN, and J. W. T. DUVEL (*Coop. Manager and Farmer*, 3 (1913), No. 2, pp. 47-49, figs. 6).—This paper reports some results of "acidity determinations that have been made on several thousand samples representing corn on the farm, as received at and shipped from country elevators and terminal markets, as loaded at seaports for export, and as discharged at foreign ports, together with representative samples of special lots of corn used in experimental work of storage, drier, and transportation, carried on by the Office of Grain Standardization [of the U. S. Department of Agriculture].

"The investigations show that there is a wide variation in the amount of acid existing in commercial corn and that this acid can be accurately measured. It establishes as a fact that corn which is sound and free from damage contains less acid than unsound or damaged corn. In a general way, the investigation also shows that the degree of acidity is directly proportional to the percentage of damage and to the commercial grading at terminal markets, and inversely proportional to the percentage of germination; that is, the lower the percentage of damage, the lower the acidity; the better the commercial grade, the lower the acidity; and the lower the percentage of germination, the higher the acidity. Drier experiments show that there is no material change in the acid content of the same corn before and after drying."

Rhodesian maize, J. A. T. WALTERS (*Rhodesia Agr. Jour.*, 11 (1913), No. 1, pp. 41-46, pls. 3).—In this article the author discusses the ear characteristics of the 2 varieties of corn chiefly grown in Rhodesia, viz, Hickory King and Salisbury White. The latter variety is a result of the union of Boone County White and White Horsetooth with Hickory King. Several features of the 8-, 10-, and 12-row types are noted, and a score card is presented.

Report on cotton cultivation, 1912, R. J. H. DELOACH (*Bul. Ga. State Col. Agr.*, 1 (1913), No. 2, pp. 7, pl. 1, figs. 2).—The work noted in this bulletin includes chiefly the testing of varieties, hybridization, and a type study of the cotton plant. This work was primarily for instructional purposes in the college.

A trial in spacing of cotton is reported in which the yields ranged from 2,000 to 3,000 lbs. per acre. The rows were 4 ft. apart. The smallest yield resulted from hills which were 3 ft. apart in the row, with 1 plant per hill, and the largest yield was from hills 18 in. apart, with 2 plants per hill.

Notes are given in regard to the cultivation of the Sunbeam variety of cotton in various parts of the State.

Cotton-seed selection for southeast Missouri, A. R. EVANS (*Missouri Sta. Circ.* 66 (1913), pp. 243-246, figs. 2).—This bulletin gives directions to growers for improving yields by planting their own selected seed.

A new forage plant, A. STOLZ (*Amer. Breeders Mag.*, 4 (1913), No. 3, pp. 162-164, fig. 1).—This describes *Desmodium hirtum* as found wild in German East Africa, and gives methods of propagation and improvement under cultivation and its uses as a cover and forage crop.

Kapok or cotton silk, H. POWELL (*Dept. Agr. Brit. East Africa Ann. Rpt.* 1911-12, pp. 91, 92).—The botanical species of this East African tree has not yet been determined. Experiments showed that 500 dry pods, including lint and seed, weighed 40 lbs., the hand-cleaned lint 8 lbs., and the seed 13 lbs.

Inoculation experiments with lupines, J. C. DE RUYTER DE WILDT and D. MOL (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat.* [Netherlands], No. 14 (1913), pp. 46-53, pls. 2).—Notes and data of pot experiments are given, in which three commercial cultures were employed with lupines in sandy soil. Irregular and unexpected results were obtained.

Experiments in the cultivation of peanuts in British India, A. CHEVALIER (*Jour. Agr. Trop.*, 13 (1913), No. 146, pp. 228-230).—Methods of cultivation are described, and tabulated data show yields, cost of production, and profits. The two early varieties tested yielded 921 kg. and 1,062 kg. of nuts in the shell, and 1,905 kg. and 1,746 kg. of straw per acre, respectively. The two late varieties yielded 842 kg. and 1,204 kg. of nuts in the shell, and 2,685 kg. and 2,757 kg. of straw per acre, respectively.

Potato culture, A. DICKENS (*Kansas Sta. Bul.* 194 (1913), pp. 473-491, figs. 4).—This bulletin discusses cultural methods for potatoes in Kansas, including crop rotation, fertilizers and manures, seed varieties, diseases and insects and their control, and spray materials and machinery.

It is noted that results of experiments at the station indicate the advantage of rotation of crops previous to a potato crop, and early fall plowing with shallow spring plowing on heavy soil.

Potato culture (*Scot. Farmer*, 21 (1913), No. 1083, pp. 939, 940).—This reports results of field tests of 11 varieties of potatoes in the vicinity of Edinburgh, Scotland, in connection with the use of muck and commercial fertilizers in the drill. Seven yards of 28-in. drills gave total yields ranging from 22 to 43 lbs., total numbers ranging from 132 to 461 tubers, and marketable tubers ranging from 60 to 107. It is noted that a dry spray has been used with great success in the production of this crop.

The effect of ferrous sulphate on the quality and quantity of potatoes, D. R. EDWARDES-KER (*Jour. Southeast Agr. Col. Wye*, No. 21 (1912), pp. 275-295, figs. 2).—This reviews the work of other investigators along this line and gives results of field experiments which did not conform closely to those quoted. The use of ferrous sulphate as a top-dressing on potatoes was found to give no increase in yield up to $\frac{3}{4}$ cwt. per acre of the iron salt, nor was there found to be any alteration of the quality of the tubers after cooking, or in the composition of their ash after incineration.

"As a tentative theory is advanced the suggestion that the effect of ferrous sulphate is considerably affected by the amount of calcium carbonate in the soil experimented upon, the larger the amount of calcium carbonate the less the effect of the ferrous sulphate. This is probably due to a chemical action between the calcium carbonate and the ferrous salt, whereby ferric oxid is produced by oxidation more quickly than would otherwise be the case."

A bibliography of 13 titles is appended.

Experiments with varieties of rice at the botanic gardens, 1912, J. B. HARRISON (*Jour. Bd. Agr. Brit. Guiana*, 7 (1913), No. 1, pp. 42, 43).—This gives the results of variety tests of rice for the period 1905–1912 in which the yields ranged from 14.9 bags (1,788 lbs.) to 42.7 bags per acre. The effect of sulphate of ammonia as a fertilizer was apparently to reduce the yield from 43.7 to 40.8 bags per acre, this being due chiefly to lodging.

Results of tests of new varieties of rice, I. E. FERRARI (*Bul. Agr. [Milan]*, 47 (1913), No. 42, pp. 1, 2).—This gives trial results of 11 new varieties of rice introduced into Italy from the Orient.

Drying rice in storage, G. Pozzi (*Bul. Agr. [Milan]*, 47 (1913), Nos. 37, p. 1; 38, pp. 1, 2; 39, pp. 1, 2).—This discusses methods of artificially drying rice placed in storage in September, October, and November, and the influence of temperature, hygroscopic moisture, and ventilation.

The cultivation of sugar beets, L. MALPEAUX (*Vie Agr. et Rurale*, 2 (1913), No. 24, pp. 691–695, figs. 4).—This article discusses methods of cultivation with special reference to time and means. It is noted that thinning should leave the best plants at regular intervals and that this work should be done early. When thinning was done on June 7, 12, and 19, the beets contained 19.6, 19.5, and 18.9 per cent of sugar, and yielded 6,350, 6,280, and 5,517 kg. per hectare, respectively. In comparing the results of a pneumatic machine and handwork in thinning, the yields for 1910 showed 15.16 per cent of sugar where hand-worked and 15.25 per cent where machine worked, and in 1912, 18.81 and 19.14 per cent, respectively, with yields per hectare in similar ratio.

The composition of sugar beets in the drought of 1911, and the influence of the following rains, J. URBAN (*Ztschr. Zuckerindus. Böhmen*, 37 (1913), No. 6, pp. 303–308).—Two hundred beets were gathered 2 days before a severe drought was broken by a period of wet weather, during which 81.7 mm. of rain fell and produced a luxuriant growth of the severely drought-affected beets. One hundred and fifty beets were also gathered on October 4 and the analyses of these compared with the analyses of the beets gathered before the rains, from which the author drew the following conclusions:

In spite of the yellow and wilted leaves, the beets gathered during the drought had not matured; this was concluded because of the large amount of total nitrogen (especially of proteid nitrogen) and alkalis and the relatively small amount of calcium that was found. Even when rains fall such dried-out beets are not in position to take up plant food at once, because of the scarcity of root hairs, but must first form root hairs from the substance of the roots before assimilation can be resumed in a normal way. The sugar-forming ability of the beets had been permanently injured by the dry weather, for with resumed growth only 0.62 gm. of sugar per 100 gm. of dry matter was produced in September, as compared with 1.82 gm. for the same period in a normal season. During the long drought considerable quantities of nonproteid nitrogen were stored in the root and during the rain period that followed were transformed into proteid nitrogen, and these changes going on at this time gave a quality to the juices of the beet that was unfavorable for the sugar manufacturers.

Statistics of sugar in the United States and its insular possessions, 1881–1912, F. ANDREWS (*U. S. Dept. Agr. Bul.* 66 (1914), pp. 25).—According to this compilation of statistics, “there was a great increase in the consumption of sugar in contiguous United States during the period covered by the bulletin, 1881–1912. . . . The average annual consumption, which in the fiscal years 1881–1885 was 46 lbs. per capita, was more than 78 lbs. in 1906–1910. The total

annual consumption increased from an average of 2,500,000,000 lbs. in 1881-1885 to practically 7,000,000,000 lbs. in 1901-1910, and in the fiscal year 1912, to a total of 7,900,000,000 lbs.

"The large increase in consumption was coincident with a greater home production. The cane-sugar output increased considerably, while beet sugar, the production of which amounted to little in the early eighties, far exceeded that of cane sugar in contiguous United States in the last few years. . . .

"The sugar supply of the United States proper has always been derived chiefly from abroad, and, even with a greatly increased home production in 1906-1910, the portion of supply received from domestic factories made only 23 per cent of the total consumption; this was more than twice the corresponding percentage for 1881-1885. The insular possessions—Hawaii, Porto Rico, and the Philippine Islands—furnished nearly 22 per cent, and the rest, amounting to 55 per cent, came from foreign countries during 1906-1910."

Tables show the production of sugar in the United States and its insular possessions; the consumption of sugar in contiguous United States and its sources; average yield of refined sugar per acre of beets or cane in contiguous United States, and of cane in Hawaii; production of cane sirup and cane molasses in the United States, 1899-1909; sugar production in Louisiana, Hawaii, and Porto Rico; production of sorghum sirup, sorghum cane, maple sugar, and sirup in the United States; monthly prices of sugar; freight rates; and international trade in sugar.

The sugar industry (*Thirteenth Census U. S., 10 (1910), pp. 471-483*).—Statistics for 1909 of the cane and the beet sugar industry of the United States, its territories and possessions are reported in detail.

Tobacco culture, W. W. GARNER (*U. S. Dept. Agr. Farmers' Bul. 571 (1914), pp. 15, figs. 4*).—This bulletin contains cultural and curing notes of several varieties of each of 3 general classes of tobacco: Cigar tobaccos, export tobaccos, and manufacturing tobaccos.

The growing of tobacco for nicotin extraction, G. H. GARRAD (*Jour. Southeast. Agr. Col. Wye, No. 19 (1910), pp. 262-317, pls. 4, fig. 1; No. 20 (1911), pp. 367-393; No. 21 (1912), pp. 429-438*).—This paper discusses the value of nicotin as an insecticide, the factors influencing the nicotin content of tobacco (variety, soil and climate, manuring, time of harvesting, and spacing of plants), the botanical characters of tobacco, and the practical management of the crop.

The results of the experiments of 1910 showed (1) that a rich soil produced a higher percentage of nicotin, (2) that an excess of nitrogenous fertilizer seemed to increase the nicotin content, (3) that spacing the plants $1\frac{1}{2}$ by 3 ft. apart gave the greatest yields of nicotin per acre, (4) that neglect to top or disbud reduced the yield of nicotin, and (5) that low topping (at 8 to 10 leaves) gave greater yields than high topping. In 1911 the reverse was true in regard to topping.

The best time to cut was found to be at maturity. Varieties of *Nicotiana rustica* seem to contain a higher percentage of nicotin than those of *N. tabacum*. It is noted that a yield of from 70 to 150 lbs. of nicotin per acre may be expected. Analytical data are given in tabular form.

The book of vetch, W. C. SMITH (*Delphi, Ind., 1912, pp. 157, pls. 25*).—The author has treated this subject with special stress upon the soil-improving qualities of the plant. The chapters cover its history, varieties, characteristics, seeds and seeding, vetch as a cover crop, vetch and bees, vetch as a green manure and as a forage plant, the bad points of vetch, and vetch and potatoes. There are also included the experiences of vetch growers in many parts of the United States.

Some varieties and strains of wheat and their yields in South Dakota, A. N. HUME and M. CHAMPLIN (*South Dakota Sta. Bul.* 146 (1913), pp. 267-296, figs. 8).—Some varieties of wheat, classified as common, durum, and Emmer, are described and illustrated with historical sketches. Tests of several varieties at Brookings, Cottonwood, Eureka, and Highmore showed Kubanka and Arnautka durum to rank first, Bearded Fife second, and Bluestem and Beardless Fife third in yield. Yields ranged from 0 to 36.7 bu. per acre for a period from 1905 to 1912.

History and culture of Marquis wheat, A. C. ARNY (*Minnesota Sta. Bul.* 137 (1914), pp. 5-8, figs. 2).—This article gives history, plant, and kernel characteristics and results of cultural tests that show this variety compared well with Velvet Chaff and Minnesota Nos. 163 and 169 in yield, weight per bushel, and maturity, especially on the heavier, more productive soils.

The trade in registered seed, L. H. NEWMAN (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 1, pp. 52-54).—It is noted that registered seed, which represents the progeny of elite stock seed that has passed the inspection of the Canadian Seed Growers' Association, outyields ordinary seed. Data received from 30 growers of Banner oats in Canada showed an average yield of 51 bu. per acre from registered seed, as compared with 43.5 bu. with ordinary seed. The former weighed 41 lbs. per bushel and the latter only 35.8 lbs.

Experiments with hard-coated clover seeds, K. MÜLLER (*Ber. Grossh. Bad. Landw. Vers. Anst. Augustenb.*, 1912, pp. 81-86).—In germination tests with alfalfa seeds, those germinating after 10 days were classed as hard-coated, and further observations up to the forty-fifth day showed in some cases as high as 84.9 per cent germination of the hard-coated seeds. By soaking both red clover and alfalfa seeds for 6 hours in water at a temperature of 34° C. (93.2° F.), increased yields of hay were secured over the untreated seed. This was attributed to the more complete germination of the hard-coated seeds.

Victory over quack grass, V. C. MILLER (*Iowa Agr.*, 14 (1913), No. 2, pp. 78, 79, fig. 1).—This describes 2 successful methods of killing quack grass. One, for large tracts, consisted in plowing the quack grass area 3 to 4 in. deep, exposing the roots to the action of the sun; and the other, for small areas, consisted in covering the area completely with tar paper for a few weeks.

HORTICULTURE.

The vegetable garden, J. G. BOYLE (*Indiana Sta. Bul.* 171 (1914), pp. 377-418, figs. 23).—In order to secure accurate information on the various garden operations the station designed and operated a vegetable garden to meet the needs of a family of 5 persons during the seasons 1910 to 1912, inclusive. The present bulletin, which discusses the arrangement, planning, and care of a vegetable garden, is based upon the results secured in the 3 years' work in the station garden.

The subject matter is discussed under the following general headings: The garden plan; varieties, seed purchasing, and seed testing; hotbeds, cold frames, and forcing boxes; management; insect and fungus control; and cost and returns.

Intensive production of the artichoke in Gironde, B. DE LA GIRODAY (*Vie Agr. et Rurale*, 3 (1914), No. 12, pp. 331-335, figs. 5).—In addition to cultural details attention is also called to the pests and diseases of the globe artichoke.

Experiments on selection and inheritance by vegetative propagation of *Allium sativum*, P. VOGLEB (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 11 (1914), No. 3, pp. 192-199, figs. 2).—In the experiments here described the author

sought to determine whether pure strains of garlic may be isolated by selection and whether having once secured these strains any further improvement could be obtained by selection. His results indicate that strains can be selected from a population of garlic plants which have a definite number of cloves to the entire bulb. Selection within these strains based on the weight of the bulbs appears to be of no value.

Varying valence of the characters of *Pisum sativum* as the blooming period progresses, E. ZEDERBAUER (*Ztschr. Pflanzenzücht.*, 2 (1914), No. 1, pp. 1-26, figs. 6).—The author presents the results of a study of F_1 and F_2 crosses of the garden pea which were conducted to determine what influence the crossing of even and uneven aged blooms has upon the offspring. Direct and reciprocal crosses were made between a green wrinkled-seeded variety and a yellow smooth-seeded variety. Crosses were also made between even aged blooms and early, middle season, and late blooms.

Although no general conclusions are drawn from the author's work the results are offered as a preliminary contribution to the subject of variability in character valence. Two forms of valence are recognized: Quantitative (räumliche) valence in which the valence of one character in relation to another is compared, and time (zeitliche) valence in which consideration is given to the varying valence in individual characters during the blooming period of a plant.

For the crosses in question it appears that one unit of a character pair is either prevalent (dominant) or subvalent (recessive) to the other. Yellow and smooth are prevalent to green and wrinkled. With reference to time valence the valence of any character appears to be at its highest in the early blooms and to diminish continually throughout the blooming period. A character, whether prevalent or subvalent, appears to have a greater influence on the progeny when transmitted by the female parent than when transmitted by the male parent.

Fruit and vegetable transportation and storage investigations of the United States Department of Agriculture, A. V. STUBENRAUCH (*Proc. Amer. Warehousemen's Assoc.*, 23 (1913), pp. 116-142).—A paper with the discussion following in which the author reviews some of the more recent investigations of the Bureau of Plant Industry along fruit transportation and storage lines.

Pruning young fruit trees, H. E. TRUAX (*Arkansas Sta. Circ.* 20 (1913), pp. 4, figs. 2).—A popular discussion of pruning methods as employed for young apple, peach, cherry, pear, and plum trees.

Apple growing (*Mass. [Bd.] Agr. Bul.* 2, 4, rev. ed. (1913), pp. 230, pls. 25, figs. 27).—The present edition of this bulletin (E. S. R., 21, p. 140) has been revised to include some of the more recent articles relating to apple culture in Massachusetts. A bibliography of literature dealing with various phases of apple culture is appended.

Apple growing in New Jersey, A. J. FARLEY (*New Jersey Stas. Circ.* 30, pp. 3-7, fig. 1).—This circular comprises a brief discussion relative to the adaptability of New Jersey for apple culture, with special reference to favorable climatic and soil conditions. A general list of varieties adapted for commercial planting in the State is also given.

Marked modifications in the form of pears, P. PASSY (*Jour. Soc. Nat. Hort. France*, 4, ser., 15 (1914), Feb., pp. 103-105, figs. 2).—The author here describes variations from the typical shape in certain varieties of pears which are growing close together. Comparison of the different normal and abnormal shaped types indicates that xenia has taken place.

Influence of foreign pollen, A. OTTO (*Illus. Schles. Monatschr. Obst, Gemüse u. Gartenbau*, 3 (1914), No. 3, pp. 48-50, fig. 1).—The author pollinated flowers

of the Angoulême pear with pollen of the Josephine of Malines pear. Although the immediate fruit resembled the male parent in size and shape, it resembled the female parent in both color and flavor. This phenomenon is attributed to xenia.

A new graft hybrid, L. DANIEL (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 21, pp. 995-997).—In the graft hybrid here described, which was observed at the base of an old pear tree grafted on quince stock, shoots possessing characters more or less intermediate between the pear and quince were found to have developed on a quince root. These shoots were located about 5 or 6 cm. beyond the root cushion and about the same distance away from the trunk of the stock.

Imported varieties of the avocado for California, K. A. RYERSON (*Pomona Col. Jour. Econ. Bot.*, 3 (1913), No. 1, pp. 424-439, figs. 11).—The author here presents a list of imported varieties of avocados now being tried out in California. Wherever possible a complete pomological description of the variety is also given.

A list of avocados originating in California has previously been noted (E. S. R., 29, p. 838).

The chemical composition of Florida oranges from October 1, 1912, to January 31, 1913, A. M. HENRY (*Fla. Quart. Bul. Dept. Agr.*, 24 (1914), No. 1, pp. 155-204, pls. 2).—The author here reports an investigation conducted in order to obtain data upon which to base a standard for ripe or mature oranges, such standard to be used in carrying out the provisions of the Florida immature citrus fruit law, the text of which is given.

In this study analyses were made of 259 samples of oranges taken from 17 localities in the State. From the data secured and here presented the author concludes that a standard of 1.25 per cent of total acid, determined as crystallized citric acid, is scientifically accurate, fair, and just to the producer and consumer alike, and of the greatest ease of practical application to the orange industry. The application of this standard is recommended and directions are given for conducting both field and laboratory tests.

Planting persimmons, H. H. HUME (*Jour. Heredity*, 5 (1914), No. 3, pp. 131-138, figs. 4).—The author's investigations have shown that with very few exceptions the varieties of the Japanese persimmon (*Diospyros kaki*) require pollenizers and that where pollenizers are planted in the orchards fertilization takes place readily by means of insects. On the other hand, it has been difficult to secure satisfactory pollenizers since in the varieties observed there is a tendency for staminate flowers to appear only at irregular intervals. The evidence at hand thus far shows that staminate flowers of *D. virginiana* will not fertilize the flowers of *D. kaki*. One tree of *D. kaki* growing at Eagle Lake, Fla., has been found to be constantly staminate. This variety has been named Gailey and is recommended as a general pollenizer for the Japanese varieties.

A planting plan is submitted which provides for 1 staminate tree to about 7 or 8 pistillate trees. It is pointed out that this proportion of staminate trees may be greatly reduced in the light of further observations.

Such seedless varieties as the Tanenashi and the Tamopan appear to set fruit well without pollination, the ovules of the former variety at least being largely sterile.

A preliminary note on the genetics of *Fragaria*, C. W. RICHARDSON (*Jour. Genetics*, 3 (1914), No. 3, pp. 171-177, pl. 1, figs. 4).—This comprises a brief progress report on some crossing experiments with strawberries which were started in 1910.

Runner×**runnerless** alpine plants gave runner-producing plants in F_1 and both runner and runnerless plants in F_2 , the runner being a marked dominant. Runnerless white-fruited plants crossed with runner-producing red-fruited plants gave red-fruited in F_1 and 70 red-fruited plants to 20 white-fruited in F_2 with no intermediates.

Vine pruning in California, I. F. T. BOLETTI (*California Sta. Bul.* 241, pp. 48, figs. 21).—This is the first of a series of two bulletins dealing with the pruning of *Vitis vinifera* varieties of grapes. The present bulletin, which discusses the principles of pruning, incorporates the experience of the older and more skillful grape growers and the result of experiments and observations of the station workers.

Under the general heading of principles of pruning consideration is given to physiological principles of pruning; winter pruning; summer pruning, including disbudding, thinning of shoots and topping of young vines, suckering, water sprouting, pinching, topping, defoliating, thinning the fruit, ringing, and cutting the surface roots; restriction and treatment of wounds; supports; pruning tools; and principle of economy.

Introductory considerations include a discussion of the results of defective pruning and the habits and characteristics of the vine, with special reference to *Vinifera* varieties.

Old and new hybrids in 1913, E. PÉE-LABY (*Jour. Soc. Cent. Agr. Haute-Garonne*, 24 (1914), No. 250, pp. 22-48).—This is the usual annual report upon various direct bearing hybrid grapes with reference to their character, growth, resistance to mildews, insect attacks, etc. (E. S. R., 28, p. 840).

Viticulture in Algeria, C. VON DER HEIDE (*Landw. Jahrb.*, 45 (1913), No. 3, pp. 439-502, pls. 2, figs. 5).—This comprises a statistical review of the grape industry in Algeria since 1850, together with information relative to viticultural practices, the grape-growing districts, varieties grown, wine making, etc.

Planting in Uganda, E. BROWN and H. H. HUNTER (*London and Dublin*, 1913, pp. XVI+176, pls. 35, figs. 9).—A guide to the establishment, culture, and management of plantations in Uganda. The subject matter embodies the experience of the authors principally in the establishment of Para rubber, coffee, and cacao plantations. Chapters dealing with insect pests and fungus diseases, together with data on the cost of establishing plantations and preparing products, are also included.

The results at the Buitenzorg Gardens with green manure crops, W. M. VAN HELTEN (*Meded. Cultuurtuin [Buitenzorg]*, No. 1 (1913), pp. 19, pls. 9; *abs. in Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, No. 1 (1914), pp. 21-24).—The results secured with various plants used as green manures during the past 4 years in plantations of coffee, rubber, cacao, etc., at the experimental gardens are reported.

The banana, its cultivation, distribution, and commercial uses, W. FAWCETT (*London*, 1913, pp. XI+287, pls. 8, figs. 10).—A handbook of information on the banana based on the author's observations and studies in Jamaica, as well as on a review of the literature of the subject. Most of the subject matter has previously appeared in the author's notes on the banana (E. S. R., 28, p. 743).

[Cacao manurial plats in Dominica], H. A. TEMPANY (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Dominica*, 1912-13, pp. 24-34, pl. 1).—As in previous years the results from the long-continued fertilizer and mulching experiments with cacao (E. S. R., 29, p. 42) show that natural organic manures, either in the form of pen manure or compost, are superior to any other form of fertilizer if they can be obtained in sufficient quantity. When sufficient organic manures are not available they may be supplemented to advantage by artificial manures containing nitrogen and phosphate.

The control of imported tea seed, C. BERNARD and J. J. B. DEUSS (*Dept. Landb., Nijr. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 22 (1913), pp. 38, figs. 6*).—This comprises a preliminary report on tests of some 30 types of British India tea seed, conducted with the view of securing a better grade of seed for planting in Java. The viability of the seed was determined both by the specific gravity test (E. S. R., 30, p. 444) and by actual germination tests. Consideration is also given to seed containers, methods of packing, etc.

Hazelnuts, E. GROSS (*Österr. Gart. Ztg., 9 (1914), No. 1, pp. 17-19*).—In continuation of previous reports (E. S. R., 28, p. 238) tabular data are given showing the yield of several different varieties of hazelnuts in 1913, as well as the total yield for each variety from the time it commenced to bear.

Our hardy perennial plants, edited by E. GRAF SILVA TAROUCA (*Unsere Freiland-Stauden. Vienna and Leipsic, 1913, 2. rev. and enl. ed., pp. 382, pls. 12, figs. 417*).—A handbook of all the known hardy, ornamental perennial plants of central Europe prepared by various authorities on the subject and issued under the auspices of the Dendrological Society of Austria-Hungary.

In part 1 consideration is given to the use of perennial plants in park and garden, alpine plants and their utilization in the garden, the more important perennial plants for general culture, new and hardy perennial plants from China, and short instructions on the culture, propagation, and care of perennial plants. In part 2 all of the perennial plants listed in the trade at the present time are arranged in alphabetic order according to species and discussed with reference to their cultural requirements, appearance, blooming time, and cultural value. Lists are then given of the best sorts for cut flowers and for forcing purposes. The plants are also arranged with reference to certain characteristics, such as their soil requirements, blooming period, color of flower and fruit, etc. The text is fully illustrated with photographic reproductions.

Our hardy conifers, edited by E. GRAF SILVA TAROUCA (*Unsere Freiland-Nadelhölzer. Vienna and Leipsic, 1913, pp. 301, pls. 12, figs. 307*).—A handbook of the coniferous trees and shrubs of central Europe prepared by various authorities and issued under the auspices of the Dendrological Society of Austria-Hungary.

Part 1 consists of a number of special articles dealing with conifers in park and garden, the conifers of China and North America, the utilization of foreign conifers for forest culture, the breeding, propagation, and culture of conifers, and pests and diseases of conifers. Part 2 contains a systematic review of the principal groups of conifers based on flower and fruit characters, and a key to the species based upon branch, bud, and leaf characters. An alphabetic enumeration is then given of species including the more important varieties and types, with brief notes on their cultural requirements, appearance, and value. Groupings are next given of forms arranged according to various characteristics, such as cultural conditions, color, size, height, shape, etc. The text is fully illustrated.

Our hardy deciduous trees and shrubs, edited by E. GRAF SILVA TAROUCA (*Unsere Freiland-Laubgehölze. Vienna and Leipsic, 1913, pp. 419, pls. 16, figs. 495*).—A handbook similar to the above in preparation and arrangement.

FORESTRY.

The training of a forester, G. PINCHOT (*Philadelphia and London, 1914, pp. 149, pls. 8*).—The purpose of this popular work is to describe the more important phases of the forester's life and the forester's work in national, state, and private forests and forest enterprises. The book is written especially for those who are contemplating forestry as a profession.

Forestry in America as reflected in *Proceedings of the Society of American Foresters*, B. MOORE (*Forestry Quart.*, 12 (1914), No. 1, pp. 47-69).—This comprises a review of the progress of American forestry as reflected in the *Proceedings of the Society of American Foresters*. The various articles appearing in the first seven volumes of the *Proceedings* are here arranged under different headings in chronological order and briefly abstracted.

Tenth annual report of the state forester [of Massachusetts], F. W. RANE (*Ann. Rpt. State Forester Mass.*, 10 (1913), pp. 114, pls. 11, fig. 1).—This is the customary review of forest operations in Massachusetts for 1913, including the work on the state nurseries and plantations, assistance rendered to private woodland owners, fire protection work, suppression of the chestnut bark disease and the gipsy and brown-tail moths, parasite work in connection with the control of these moths, new legislation, and a financial statement for the year.

A glimpse of **Austrian forestry**, T. S. WOOLSEY, JR. (*Proc. Soc. Amer. Foresters*, 9 (1914), No. 1, pp. 7-37, pls. 9).—A descriptive account of forestry methods in Austria, including considerable information relative to the administration of Austrian forests.

A statistical review of the forest administration of the Grand Duchy of Baden for the year 1912 (*Statist. Nachr. Forstverw. Baden*, 35 (1912), pp. XXXIII+183, figs. 11).—This is the customary statistical report on the administration, management, and exploitation of the crown, community, and corporation forests of the Grand Duchy of Baden during 1912. Data are given on forest areas, various operations in the forests, yields in major and minor forest products, and financial returns. Comparative data are also given showing the net returns from the crown forests for each of the previous 45 years.

Report of the forestry department for the year ended June 30, 1913, R. DALRYMPLE-HAY (*Rpt. Forestry Dept. N. S. Wales*, 1913, pp. 24, pls. 6).—In addition to a progress report of forest operations in New South Wales, including a financial statement for the year ended June 30, 1913, the following three departmental bulletins are appended: *Climatic Influence of Forests*, by L. A. Fosbery; *The Forests of the Bellinger River*, by E. H. F. Swain; and *Reafforestation of Depleted Hardwood Areas in the Coastal Districts of New South Wales*, by C. J. Clulee.

Climatic characteristics of forest types in the central Rocky Mountains, C. G. BATES, F. B. NOTESTEIN, and P. KEPLINGER (*Proc. Soc. Amer. Foresters*, 9 (1914), No. 1, pp. 78-94).—This comprises a progress report on an experiment which was started under the direction of the Forest Service of the U. S. Department of Agriculture at the Fremont Experiment Station in 1910 and at the Wagon Wheel Gap Experiment Station in 1911 to compare the climatic characteristics of the various forest types which occur in two localities of southeastern and southwestern Colorado for a short term of years, and to compare the characteristics of similar types in the two localities for a long term of years.

The relation of the surface cover and ground litter in a forest to erosion, M. J. GLEISSNER (*Forestry Quart.*, 12 (1914), No. 1, pp. 37-40).—The author cites the experience in a Bavarian forest to show that the constant removal of forest litter is an important cause of erosion on hillsides. The prevention of erosion under these conditions by the construction of a series of horizontal transverse ditches is here described.

Effective fertilizers in nurseries, G. A. RETAN (*Forestry Quart.*, 12 (1914), No. 1, pp. 34-36).—As a result of fertilizer experiments which have been conducted in two nurseries of the Pennsylvania department of forestry for the past three seasons the author concludes that chemical fertilizers can best be

applied in connection with a green crop planted preliminary to starting forest seed beds.

Some Douglas fir plantations.—IV, Tortworth Wood, Gloucestershire (*Jour. Bd. Agr. [London]*, 20 (1914), No. 10, pp. 865-875, figs. 2).—In continuation of previous observations on Douglas fir plantations (E. S. R., 30, p. 446) a record including growth and yield tables is given for a small Douglas fir stand, part of which was planted in 1872 and part in 1883.

Protomorphic shoots in the genus *Pinus*, A. G. HARPER (*Quart. Jour. Forestry*, 8 (1914), No. 2, pp. 101-106, fig. 1).—The author here records some personal observations on the occurrence of protomorphic shoots in various species of the genus *Pinus* and gives a brief bibliography of references to the subject.

Ray tracheids in *Sequoia sempervirens* and their pathological character, W. S. JONES (*Quart. Jour. Forestry*, 8 (1914), No. 2, pp. 81-94, pls. 3, figs. 6).—The author here describes in detail ray tracheids which have been observed a number of times in the wood of *S. sempervirens*.

Cost accounts for reconnaissance surveys, A. B. CONNELL (*Forestry Quart.*, 12 (1914), No. 1, pp. 44-46).—A system of cost accounting to be applied in making reconnaissance surveys is here described in detail.

Graded volume tables for Vermont hardwoods, I. W. BAILEY and P. C. HEALD (*Forestry Quart.*, 12 (1914), No. 1, pp. 5-23).—The authors here present and discuss graded log scales and volume tables for beech, hard maple, and yellow birch based on measurements of 1,200 trees in the woods and 3,500 logs in the mill. They conclude from their investigation that local volume tables can be prepared rapidly and economically if based upon mill tallies made from all merchantable logs.

Forest products of Canada, 1911.—Poles and cross-ties, R. G. LEWIS and W. G. H. BOYCE (*Dept. Int. Canada, Forestry Branch Bul.* 35, rev. ed. (1914), pp. 17).—A previous edition of this bulletin has been noted (E. S. R., 28, p. 645).

[The wood industry] (*Thirteenth Census U. S.*, 10 (1910), pp. 619-623).—The statistics of 1909 are compared with those of previous years with reference to the destructive distillation of wood industries and their products.

Turpentine and rosin industry (*Thirteenth Census U. S.*, 10 (1910), pp. 679-694).—"This report covers the production of commercial spirits of turpentine and rosin by the distillation of the resinous exudation of the pine tree, the crude resin being derived from the longleaf pine (*Pinus palustris*), which is indigenous to a large coastal area stretching from North Carolina to eastern Texas, and, to a less extent, from the Cuban or slash pine (*P. heterophylla*), and the loblolly pine (*P. taeda*)."

The rubber and resin content of the desert rubber plant "guayule" in relation to rainfall, F. E. LLOYD (*Jour. Soc. Chem. Indus.*, 33 (1914), No. 3, pp. 107-109).—In continuation of his previous investigations (E. S. R., 25, p. 844), relative to guayule (*Parthenium argentatum*), the author here discusses the effect of varying rainfall on the rubber and resin content of the guayule plant.

From the data at hand the conclusion is reached that a relatively abundant amount of rainfall results in a plant which simulates in many ways one grown under irrigation, the likeness extending to the amount of rubber produced and the relative volumes of bearing and nonbearing tissues. Plants grown under these conditions yield a distinctly less amount of rubber than a typical desert plant. Within the normal habitat of the guayule plant the amount of rubber varies fully 62 per cent. The amount of resin secreted appears not to be affected by the amount of soil water. Evidence is yet lacking that rubber and resin secretion are casually related in the plant.

DISEASES OF PLANTS.

The enemies of cultivated plants, G. TRUFFAUT (*Les Ennemis des Plantes Cultivées. Paris, 1912, pp. 565, pls. 55, figs. 374*).—In this book the author describes the principal fungus and insect pests of plants. By means of a system of keys it is possible to recognize any pest. The keys are grouped under an alphabetical arrangement of the host plants, and the different parasites by their sequence of families. Chapters are given on methods of treatment for the prevention of attack, these including the use of fungicides and insecticides, natural methods of repression, etc. Formulas are given for the preparation of the different mixtures, and methods for their proper application are indicated.

Mildews, rusts, and smuts, G. and IVY MASSEE (*London, 1913, pp. 229, pls. 5*).—In this book the authors describe the mildews, rusts, and smuts occurring in Great Britain, and in addition they have included a number of species not yet been definitely reported in Great Britain, but parasitic on host plants indigenous to the country and also those parasitic on cultivated plants. After an introduction on the nature of the fungi, they consider the general characteristics of the different families, their relationship, the method by which fungi gain entrance into the host plant, etc., and give keys to the genera and species of the families Peronosporaceæ, Erysiphaceæ, Perisporiaceæ, Uredinaceæ, and Ustilaginaceæ.

The British rust fungi, W. B. GROVE (*Cambridge, 1913, pp. XII+412, figs. 290*).—The author presents a systematic study of the rust fungi of Great Britain, more than 250 species being included. The life history of *Puccinia caricis* is described at length as an illustration of the complexity of the group, after which chapters are given discussing the sexuality of the Uredinales, alternate generations, spore forms, grouping according to spore forms, etc. The life histories of a number of other species are described, among them *P. graminis*, *P. poarum*, *P. malvacearum*, *Gymnosporangium clavariaforme*, *Endophyllum sempervivi*, *Cronartium ribicola*, *Melampsora pinitorqua*, and *Calyptospora goeppertiana*, which represent the principal types of rust. An extended discussion of specialization and immunity is also given.

The principal portion of the work is taken up with the systematic treatment of the rusts. A considerable number of forms that are closely allied are grouped together, the author not believing in segregating species on wholly biological differences.

Notes on *Uredinopsis mirabilis* and other rusts, W. P. FRASER (*Mycologia, 6 (1914), No. 1, pp. 25-28*).—The author reports that five sowings of teliospores of *U. mirabilis* from *Onoclea sensibilis* on *Abies balsamea* were successful, as were also three sowings of æciospores on *O. sensibilis*, but infection failed with *Osmunda claytoniana*, *O. regalis*, *Aspidium thelypteris*, *Asplenium filix-femina*, and *Phegopteris dryopteris*. Teliospores of *Melampsora medusæ* from *Populus grandidentata* infected *Tsuga canadensis*, but not *Larix laricina*. Teliospores of *Pucciniastrum myrtilli* from *Gaylussacia resinosa* infected *T. canadensis*. Teliospores of *Calyptospora columnaris* from *Vaccinium pennsylvanicum* infected *Abies balsamea*. *Peridermium harknessii* failed to infect *Comandra umbellata*.

Two parasitic plants, KRÄNZLIN (*Pflanzer, 9 (1913), No. 11, pp. 556-568, pls. 3*).—This includes a description and brief account of the habits and relations of *Cassytha filiformis*, also of a *Loranthus* showing close affinities with *L. dregei*. Removal of plants or parts attacked by these parasites is the only remedy suggested.

Plus and minus strains in the genus *Glomerella*, C. W. EDGERTON (*Abs. in Science, n. ser., 39 (1914), No. 998, p. 258*).—In a previous publication (E. S. R.,

26, p. 645) the author called attention to what he called plus and minus strains of this fungus. These strains have been carried over for three years and are said to be still producing perithecia abundantly. That fertilization has taken place between the two strains has been proved by isolating single asci from the boundary line between the two strains and allowing them to grow into colonies. These colonies usually produce both strains.

Root knot, gall worms, and eelworms, C. FULLER (*Agr. Jour. Union So. Africa*, 6 (1913), Nos. 3, pp. 440-448, figs. 4; 5, pp. 792-802, figs. 6).—This is a brief and somewhat general account of the life history and habits of several nematodes attacking economic plants, chiefly in South Africa. Recommendations looking to the control of these pests emphasizes efforts to develop nonsusceptible strains from plants found to be already measurably resistant.

Root knot—cause and control, L. CHILDS (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 12, pp. 737-756, figs. 8).—This is a somewhat general account of the distribution, life history, and work of *Heterodera radiculicola*, giving a list of nearly 500 plant hosts of this nematode and discussing means of control, which include appropriate fertilization, cultivation, starvation, drought, flooding, carbon bisulphid, formaldehyde, and steam.

Nematodes attacking wood rushes in Silesia, O. OBERSTEIN (*Ztschr. Pflanzenkrankh.*, 23 (1913), No. 5, pp. 262-264, figs. 2; abs. in *Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 10, p. 1662).—The author notes the discovery by A. Lingelsheim, in the spring of 1913, of *Heterodera radiculicola* in nodules found on roots of *Scirpus sylvaticus* in the Botanical Gardens at Breslau.

[Report on plant diseases], M. T. COOK (*Ann. Rpt. N. J. Bd. Agr.*, 40 (1912), pp. 236-240).—This report deals briefly with some diseases noted in connection with vegetables, fruits, berries, ornamental trees, and flowers; and at somewhat greater length with the blister rust of white pine (*Peridermium strobi*) and the chestnut bark disease, listing several publications on plant diseases issued in 1912.

Plant diseases and pests, G. AUCHINLECK (*Imp. Dept. Agr. West Indies, Rpts. Bot. Sta. [etc.] Grenada*, 1912-13, pp. 8, 9).—Giving a brief account of insects affecting economic plants in Grenada during the past 3 years, and noting that the fungus *Sphaerostilbe* decreased greatly black blight of citrus trees due to scale insects in 1913, the author mentions also some sporadic cases of a disease of coconut, suspected to be bud rot, as observed during the past year.

Cryptogamic diseases in Hungary, B. PATER (*Ztschr. Pflanzenkrankh.*, 23 (1913), No. 5, pp. 260-262; abs. in *Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 10, pp. 1656, 1657).—The author notes briefly the appearance and relative activity in Hungary of the following organisms in 1912: *Puccinia graminis*, on rye, *P. malvacearum* on *Althea officinalis*, *P. bullata* on *Conium maculatum*, *P. menthae* on *Mentha canadensis*, *piperascens*, *Epichloe typhina* on *Agropyrum repens*, *Plasmopara nivea* on *C. maculatum*, *Phoma faniculina* on fennel, and *Oidium quercinum* on oaks since 1910, old trees appearing to be immune.

Parasitic fungi observed in the vicinity of Turin in 1911, P. VOGLINO (*Ann. R. Accad. Agr. Torino*, 55 (1912), pp. 199-227).—Notes are given of a large number of fungi found parasitic on various plants and the following new species are described: *Sphaeronema parasiticum* on the leaves of *Crataegus glabra*, *Coniothyrium opuntiae* on *Opuntia ficus indica*, and *Ascochyta laricina* on larch seedlings.

Mycological notes, B. G. C. BOLLAND (*Agr. Jour. Egypt*, 3 (1913), No. 1, pp. 28-30, pl. 1).—The author gives brief descriptions of some plant diseases as noted in Egypt. Withertip of citrus fruits, particularly common on orange

trees, is described. Spraying with Bordeaux mixture, pruning, good cultivation, and proper nourishment, are insisted upon. It is stated that in Egypt wheat is attacked chiefly by *Ustilago tritici* and barley by *U. hordei* and *U. nuda*.

Plant diseases in South Africa, I. B. P. EVANS (*Agr. Jour. Union So. Africa*, 6 (1913), No. 3, pp. 449-455, figs. 3).—Besides brief notes regarding the new phytopathological laboratory at Pretoria, general mention is made of investigations in progress there. Reference is made to some diseases peculiar to the country, such as a bacterial disease of mango prevalent in the Transvaal and Natal, also to some fungi parasitic on native plants.

Plant diseases in Java, L. P. DE BUSSY (*Meded. Deli-Proefstat. Medan*, 8 (1913), No. 2, pp. 64-68, 82).—Reference herein is made chiefly to studies already reported by Honing (E. S. R., 27, p. 136) and those noted below.

Bacterial forms obtained from tobacco and other plants showing gummosis, J. A. HONING (*Meded. Deli-Proefstat. Medan*, 7 (1912), No. 6, pp. 223-253, fig. 1).—As contributory to the study of the general question whether bacterial gummosis may be ascribed to activity of forms other than *Bacillus solanacearum*, the author reports on the physiological and morphological study of a number of bacteria obtained from tobacco, etc. Of these, eleven are described as new species under the following names: *Bacterium schöffneri*, *B. zinniioides*, *B. sumatranum*, *B. aurantium-roseum*, *B. stalactitigenes*, *B. deliense*, *B. patelli-forme*, *B. rangiferinum*, *B. langkatense*, *B. medanense*, and *Corynebacterium piriforme*.

Vegetable pathology, E. JARVIS (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1912-13, pp. 98-100).—Along with brief notes on diseases already more or less familiar in Queensland, mention is made of a banana disease of undetermined cause said to be more severe on wet lands; some physiological abnormalities of potato; a new outbreak of *Phytophthora infestans* on tubers after immunity for a year; and a disease of cucurbitaceous plants ascribed to a *Phoma* of undetermined species.

Influence of light on infection of certain hosts by powdery mildews, G. M. REED (*Abstr. in Science, n. ser.*, 39 (1914), No. 999, pp. 294, 295).—The author reports results of investigations to determine the influence of light upon infection of hosts by powdery mildew. Seedlings of barley and wheat that had been grown in darkness until the first leaf was from 2 to 3 cm. long were inoculated with the mildew from their respective hosts. Some of the inoculated plants were kept continuously in the dark, others were removed at once and placed in the light, while still others were retained in the dark for intervals of 24 hours before being placed in the light. In general the period of incubation was retarded proportionally to the time the plant was kept in the dark. In other series of experiments the plants were first grown in the light and then after inoculation placed in the dark, some immediately, others at intervals of 24 hours.

In the case of plants placed at once in the dark no infection occurred, while those kept in the light for a day or two became infected. The period of the incubation of the fungus, however, was materially retarded. The author states that in general the effect of the absence of light on the mildew may be considered as an indirect one. Infection fails to occur in those cells which have not developed chlorophyll. This indicates that the mildew is a strict parasite attacking cells which are not capable of carrying on their normal functions.

These results are quite different from those obtained by inoculating etiolated plants with saprophytic fungi, as under such conditions the saprophytes are able to develop on the living tissues.

Investigation on foot disease of cereals, A. GUERREPAIN and A. DEMOLON (*Betterave*, 23 (1913), Nos. 597, pp. 386-388, fig. 1; 598, pp. 402-405; 24 (1914),

No. 599, pp. 7, 8).—The results of an investigation of the disease of cereals due to *Ophiobolus graminis* and *Leptosphaeria herpotrichioides* are given, in which the influence of temperature, rainfall, soils, cultural conditions, varieties, etc., on the occurrence of the disease and results of experiments for the control of the fungi are described.

The authors claim that there are no known means for preventing the attack, but that certain factors favor or retard the development of the disease. Abnormally high winter temperatures, excessive growth of winter wheat at the beginning of the growing period, early seeding, the excessive use of nitrogenous fertilizers, susceptible varieties, and the too frequent seeding of the ground with wheat all favor the development of the fungi. Late, but not too late seeding, slow growth before winter, the avoidance of the excessive use of fertilizers and of manures containing infected straw, and the adoption of rotations in which nonsusceptible crops, such as alfalfa, are introduced, tend to reduce liability to attack and loss from this disease.

The quality of the 1913 grain for seed purposes, L. HILTNER and G. GENTNER (*Prakt. Bl. Pflanzenbau u. Schutz*, n. ser., 11 (1913), No. 12, pp. 145-148, fig. 1).—The authors state that numerous tests of seed sent from various parts of Bavaria showed for 1913 a high degree of *Fusarium* infection for wheat, oats, and rye. This is said to be more severe on the winter wheat and rye.

Smut experiments, R. E. SOUTTER (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1912-13, pp. 111, 112; *Queensland Agr. Jour.*, 30 (1913), Nos. 2, pp. 97-99; 3, pp. 162, 163).—These tests were carried out at the Bungeworgorai State Farm, Roma.

Of the 31 varieties of wheat tested for resistance, 26 gave from 25 to 94 per cent free from smut. The remaining 5 were entirely free from smut, one of these, Florence, being about the earliest flowering variety grown in that section. Arsenic seed treatment continued to give favorable results as regards germination, infection, and reinfection. The salt and sheep dip treatments were discontinued as being of no value.

Development of beet mildew, G. FRON (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 48, pp. 686, 687).—The author gives briefly the results of observations regarding the influence of unfavorable meteorological conditions during recent winters as related to the activity of *Peronospora schachtii*, which has inflicted serious injury in late years upon the beet crops in northern France.

Development of beet mildew in 1912-13, G. FRON (*Bul. Soc. Nat. Agr. France*, 73 (1913), No. 9, pp. 709-712).—This note, presented by Hitier, states that weather conditions described as prevalent near Montdidier during the last two years have favored the successful wintering of *Peronospora schachtii* and early and profuse distribution of its spores.

The systematic position of the organism of the common potato scab, H. T. GÜSSOW (*Science*, n. ser., 39 (1914), No. 1003, pp. 431-433).—While studying the organism that causes the scab of potatoes, an attempt was made to determine the proper name for the fungus provisionally described by Thaxter as *Oospora scabies* (*E. S. R.*, 3, p. 772). Following international rules the author claims the name for the organism should be *Actinomyces scabies*.

Foliage resistance of different varieties of potatoes to *Phytophthora infestans*, I. E. MELHUS (*Abs. in Science*, n. ser., 39 (1914), No. 998, pp. 257, 258).—The author describes a method in which varietal resistance of potatoes to *P. infestans* was studied by artificially infecting the foliage.

The plants are grown in a greenhouse under conditions supposed to be favorable for the development of the fungus, the conidia of the fungus are germinated in water under optimum temperature conditions, and the resulting zoospores sprayed on the lower surfaces of the healthy leaves of vigorous plants from 6

to 12 in. tall. Plants thus treated are held in a moist atmosphere at 20 to 25° C. (68 to 77° F.) over night and removed the following morning.

It is believed that by this method it will be possible to learn the relative resistance of any variety of potato without growing it under field conditions.

Production of tobacco varieties resistant to slime bacteria, J. A. HONING (*Meded. Deli-Procstat. Medan*, 8 (1913), No. 1, pp. 12-21).—In a preliminary report of further work (E. S. R., 28, p. 446), the author states that of 87 selected varieties of tobacco from Java, Cuba, Mexico, the United States, Brazil, Paraguay, Dominican Republic, the Philippines, Japan, and Hawaii all proved to be susceptible to *Bacillus solanacearum*, showing bacterial gummosis. Some Deli varieties were somewhat less affected, as appeared to be also two from the Philippines and one from Japan. These are discussed as a possible source for the development of more resistant varieties.

Tomato leaf spot, H. C. LONG (*Gard. Chron.*, 3. ser., 54 (1913), No. 1407, pp. 417, 418, fig. 1).—Reviewing briefly the history of *Septoria lycopersici*, causing leaf spot of tomatoes in England since 1907, the author approves the remedial measures recommended by Güssow (E. S. R., 20, p. 346).

A new disease of tomatoes, P. VOGLAND (*Ann. R. Accad. Agr. Torino*, 55 (1912), pp. 379-381).—The author describes *Cladosporium fulvum violaceum*, a new variety parasitic on tomato leaves. It is differentiated from the typical species mainly by the violet colored mycelium and conidiophores, characters which were maintained in cultures of the fungus.

Diseases of pear and apple trees, P. PASSY (*Jour. Soc. Nat. Hort. France*, 4. ser., 14 (1913), Dec., pp. 781, 782).—To a brief discussion of the pear disease the author adds a description of water core in apples, the glassy portions showing early attack by worms.

Treatment of chlorosis in fruit trees, G. RIVIÈRE and G. BAILHACHE (*Jour. Soc. Nat. Hort. France*, 4. ser., 14 (1913), May, pp. 287, 288).—It is stated that besides supporting conclusions from experiments previously noted (E. S. R., 27, p. 48), this study, carried out with apple and pear trees, seems to show that the favorable results observed in connection with use of iron sulphate are attributable to the metallic component of this salt, and not to the sulphuric acid.

Restoration of color to etiolated plants, L. GODDE (*Jour. Soc. Nat. Hort. France*, 4. ser., 14 (1913), May, pp. 290, 291).—Discussing some disadvantages ascribed to use of iron sulphate for chlorosis of fruit trees, etc., the author recommends a formula employing potassium sulphate, iron filings, and copper chips in the proportion of 76:6:1.

Fungus gummosis, H. S. FAWCETT (*Cal. Cult.*, 42 (1914), No. 4, pp. 99-102).—Including under the term gummosis all gumming formations and exudations of a somewhat permanent character, whether due to unfavorable climatic conditions or to parasitic invasion, the author discusses some work of other investigators on stone fruit and citrus trees, also some of his own relating more particularly to the latter.

It is stated that a bacterium (*Pseudomonas cerasus*) is at least partially responsible for cherry gummosis, which it is said may be largely prevented by budding in the limbs of Mazzard cherries as stocks, or limited by cutting out and disinfecting diseased areas. Apricot gumming receives much the same general treatment. At least five kinds of gum diseases of citrus trees are known in California (2 of which are ascribed to fungi), some account of these being given with treatments adapted to particular forms. The brown rot gummosis is ascribed to *Pythiacystis citrophthora* and the gray rot gummosis to *Botrytis vulgaris*.

A contribution to the life history and physiology of *Cylindrosporium* on stone fruits, B. B. HIGGINS (*Abs. in Science, n. ser.*, 39 (1914), No. 998, p. 258).—A study of this fungus has brought to light an interesting condition of polymorphism. Four spore forms were found to be genetically connected in the life cycle, and all of these except the microconidia, are capable of infecting the host plants.

From a study of the morphological and biological characters of the organism from eight species of *Prunus* it is found that the forms fall naturally into three species, each of which is present on one of three more or less distinct divisions of the host genus.

Some observations on the anatomy and other features of the black knot, A. STEWART (*Abs. in Science, n. ser.*, 39 (1914), No. 999, p. 291).—A description is given of the changes induced in the wood of *Prunus virginiana* by the fungus *Plowrightia morbosa*.

The normal wood of *P. virginiana* is said to contain usually rays from 1 to 4 cells wide in cross section. As a result of the stimulating action of the fungus these rays become much broader, simulating the structure of compound rays. The production of the usual elements of the xylem is greatly inhibited during the first season's growth of the knot, but there is a correspondingly great production of xylem parenchyma which is almost absent from normal wood. By a further increase in the size of the parenchyma cells the knot is greatly enlarged during the second season of its development. There is apparently no abnormal growth in the outer portion of the bark and it is sloughed off just before the conidia are produced.

Peach leaf curl, A. J. FARLEY (*New Jersey Stat. Circ.* 29, pp. 3, pls. 2).—A description is given of the peach leaf curl due to *Exoascus deformans*. For its control the author recommends a thorough spraying with concentrated lime sulphur before the buds open in the spring. Bordeaux mixture applied early in the spring before the buds start, it is said, will also control leaf curl, but the use of lime-sulphur mixture is preferred as it will control the San José scale as well as the peach leaf curl. A solution of lime sulphur of not less than 1.03 sp. gr. is recommended for use.

A disease of gooseberry new in France, E. FOEX (*Jour. Soc. Nat. Hort. France*, 4. ser., 14 (1913), Dec., pp. 775-778; *abs. in Jour. Agr. Prat., n. ser.*, 26 (1913), No. 49, pp. 717-719).—Briefly reviewing the appearance and the history since 1900 of American gooseberry mildew (*Sphaerotheca mors-uvæ*) in the British Isles and parts of Europe, the author states that among means found effective in combating this disease are cutting and burning all affected parts, turning the soil, and spraying in autumn with 3 per cent Bordeaux mixture and in spring and summer with 0.2 or 0.3 per cent potassium sulphid.

Cacao spraying trials, G. AUCHINLECK (*Imp. Dept. Agr. West Indies, Rpts. Bot. Sta. [etc.] Grenada, 1912-13, pp. 4, 5*).—Trials made in 1912 indicated that epiphytic growths on trunks of cacao trees in wet districts could probably be prevented for some years to come by 2 or 3 applications to the bark of a solution consisting of 4 lbs. copper sulphate to 50 gal. of water. Use of Bordeaux mixture, 4:4:50, did not appear to be very profitable as used on fungus diseases in Grenada, but the experiments were to be repeated in 1913.

Review of coffee diseases in Surinam, J. KUYPER (*Dept. Landb. Suriname Bul.* 31 (1913), pp. 1-16, pls. 4).—This is a brief descriptive review of diseases affecting coffee trees in Surinam since about 1900, among which are a root disease of undetermined cause; a silver thread disease said to be identical with a disease noted in Porto Rico, but not with a thread disease somewhat similar in

Java; and several leaf diseases, each associated with *Coremium* sp., *Cercospora coffeicola*, *Mycosphaerella coffea*, *Phyllosticta coffeicola*, or *Leptosphaeria* sp.

Some cases of parasitism by higher plants and by animals are also noted.

Forest tree diseases common in California and Nevada, E. P. MEINECKE (U. S. Dept. Agr., Forest Serv., *Forest Tree Diseases Common in California and Nevada* (1914), pp. 67, pls. 24).—This manual, designed for practical use in the field, discusses some of the more important tree diseases found in California and parts of Nevada, although many of them are common in other forest regions. Its aim is to enable the field man to determine the cause of the commoner diseases and injuries and to understand their effect on the living tree. It discusses also ways and means of control of fungi and mistletoes, as well as climatic, biological, and soil conditions which contribute to diseases in forest trees.

Primitive characters recalled by the chestnut bark disease and other stimuli, I. W. BAILEY and J. S. AMES (*Abs. in Science*, n. ser., 39 (1914), No. 999, p. 290).—The authors report that the common American chestnut, when attacked by the chestnut bark disease (*Endothia parasitica*), frequently produces leaves that closely resemble those of the red oak (*Quercus rubra*). This reversion is not confined entirely to external characters, for the wood formed by the diseased cambium possesses anatomical structures which are a characteristic feature of the genus *Quercus*.

Aerial galls of the mesquite, F. D. HEALD (*Mycologia*, 6 (1914), No. 1, pp. 37, 38, fig. 1).—In this brief account of 40 inoculations of mesquite with cultures of *Bacterium tumefaciens*, the author states that 10 per cent resulted in production of galls of various sizes and forms described, while the controls showed no abnormal growth in any case. This is suspected to have a bearing upon the origin of the aerial galls common on mesquite throughout the southwest.

Bacteriosis of oleander, A. TONELLI (*Ann. R. Accad. Agr. Torino*, 55 (1912), pp. 383-400, fig. 1).—The author gives a more detailed account of his investigations on this disease, previously noted (E. S. R., 29, p. 156), and shows that it is caused by *Bacillus savastanoi* and that the infection is carried to a considerable degree by various insects.

For the control of the disease cutting out the cankers, making the cuts 5 or 6 in. below the diseased area and covering the wounds with some fungicide, are recommended. Attention also should be paid to the insect pests by which the disease is spread.

A die-back disease of Douglas spruce produced by a variety of *Sphaeropsis ellisii*, L. PETRI (*Ann. Mycol.*, 11 (1913), No. 3, pp. 278-280, figs. 3; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 10, p. 1660).—The author reports a study made on a die-back disease of *Pseudotsuga douglasii* 5 to 7 years old growing in sandy soil at an elevation of 1,000 ft. in Tuscany. The fungus is claimed to be a variety of *S. ellisii*. The susceptibility of the trees attacked is considered to be due to the excessive moisture, insufficient light, and low temperature in this location, as trees nearby, but more favorably situated in these respects, were perfectly healthy. It is suggested that the fungus was spread from *Pinus sylvestris* in the neighborhood.

Spread of infection was prevented by spraying with 1 per cent Bordeaux mixture.

The parasitism of *Gnomonia veneta* on the sycamore, A. TONELLI (*Ann. R. Accad. Agr. Torino*, 55 (1912), pp. 401-414, figs. 2).—This article in a briefer form has been previously noted (E. S. R., 30, p. 350).

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Illustrated bird dictionary and note book: Land birds of eastern North America, C. A. REED (*Garden City, N. Y.*, [1912], pp. 110, figs. 91).—This small handbook lists the birds common to eastern North America with brief notes on their appearance, habits, nests, etc. Nearly all the common species are figured in pen and ink sketches.

Illustrated bird dictionary and note book: Water birds, game birds, and birds of prey, C. A. REED (*Garden City, N. Y.*, 1912, pp. 127, figs. 115).—This small handbook gives pen and ink sketches and descriptions of water birds, game birds, and birds of prey.

Western bird guide: Birds of the Rockies and west to the Pacific, C. A. REED, H. F. HARVEY, and R. I. BRASHER (*Garden City, N. Y.*, 1913, pp. 252, figs. 233).—This small pocket guide, illustrated in color, describes the birds of the Rockies and Pacific coast.

The birds of Kansas, C. D. BUNKER (*Kans. Univ. Sci. Bul.*, 7 (1913), No. 5, pp. 137-158).—This paper lists 379 species.

Hygrophily and phototropism in insects, F. PICARD (*Bul. Sci. France et Belg.*, 46 (1912), No. 3, pp. 235-247).—A brief discussion of the subject.

The insect enemies of cultivated plants, G. TRUFFAUT (*In Les Ennemis des Plantes Cultivées. Paris*, 1912, pp. 223-424, pls. 45, figs. 275).—Following a discussion of the measures employed in combating insect pests, brief accounts are given of the more important insect enemies of cultivated plants, arranged by orders.

[Insect pests in Nova Scotia], R. MATHESON (*Dept. Agr. Nova Scotia*, 1913, *Buls.* 3, pp. 16, figs. 3; 4, pp. 14; 5, pp. 36, pls. 2, figs. 4).—These bulletins relate respectively to the present status of the San José scale in Nova Scotia; the injurious insect, pest and plant disease act, 1911, and regulations issued thereunder; and the brown-tail and gipsy moths.

Insects of Florida: I, Diptera, C. W. JOHNSON (*Bul. Amer. Mus. Nat. Hist.*, 32 (1913), pp. 37-90).—The present paper, which lists 845 species of Diptera, supplements a list published in 1895^a which contained about 450 determined species.

[Insect pests in St. Vincent], H. A. BALLOU (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Vincent*, 1912-13, pp. 11-17).—This report is based upon investigations made from October 13 to November 1, 1913, and relates to the occurrence of insect enemies of cotton, coconuts, cacao, arrowroot, limes, peanuts, cassava, pigeon peas, etc.

Summary of entomological information in the year 1913 (*Agr. News [Barbados]*, 13 (1914), Nos. 306, p. 26; 307, p. 42; 308, p. 58).—This is a summarized account of the occurrence of insect pests of the year.

Notes on insect enemies of tropical agriculture, F. ZACHER (*Tropenpflanzer*, 17 (1913), No. 3, pp. 131-144, figs. 12).—This paper consists of miscellaneous notes on a number of pests, including crickets as enemies of *Kickxia* rubber, enemies of cotton in the Bismarck Archipelago, xylophagous enemies of cotton in Africa, tobacco pests, and a forest pest (*Sylepta* sp.) in North Togo.

Notes on the insect enemies of tropical agriculture, F. ZACHER (*Tropenpflanzer*, 17 (1913), No. 6, pp. 305-315, figs. 3).—This paper relates to the cottony cushion-scale (*Icerya purchasi*), which appears to have been collected in German Southwest Africa.

Report of the entomologist, W. H. PATTERSON (*Govt. Gold Coast, Rpt. Agr. Dept.*, 1912, pp. 22-25).—This report deals largely with the occurrence of insect pests during the year 1912.

Report of the bureau of entomology, Stavropol, for the year 1912, B. UVAROV (*Otchet Dîrûatel. Stavropol. Ent. Bûro, 1912, pp. 32, figs. 6; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 11, pp. 459-461*).—This report relates to the occurrence of the more important insect enemies and the work of combating them.

Seeking insects in the Orient, H. S. SMITH (*Cal. Cult., 42 (1914), No. 5, pp. 132-134*).—This is a report of observations of the occurrence of insect pests and insect parasites during the course of a trip made to the Orient with the view to discovering and introducing mealy bug parasites.

Recent importations of beneficial insects in California, E. J. VOSLER (*Mo. Bul. Com. Hort. Cal., 2 (1913), No. 12, p. 770*).—*Lecaniobius cockerelli*, an egg parasite of the black scale, is said to have been imported from the West Indies; several hymenopterous parasites of mealy bugs from Japan; a parasite of the red scale and a pteromalid egg parasite of the black scale from the Philippines; and parasites of the black scale from Peru.

Insect pests of the potato, C. FRENCH, JR. (In *Handbook of Fungus Diseases of the Potato in Australia and Their Treatment. Melbourne, 1911, pp. 212F-212U, figs. 14; Jour. Dept. Agr. Victoria, 11 (1913), No. 12, pp. 729-748, figs. 14*).—This summarized account of the important insect enemies of the potato in Australia appeared as an appendix to the work by D. McAlpine, previously noted (E. S. R., 30, p. 48).

It is stated that the native insects whose natural food is being destroyed as new land is being brought under cultivation are turning their attention to the potato and other crops. Among the several more important species mentioned are *Thrips tabaci*, several species of cutworms and looper caterpillars, the potato moth (*Lita solanella*), the potato and tomato weevil (*Desiantha nociva*), wireworms, etc.

Insect pests of paddy in southern India, T. B. FLETCHER (*Dept. Agr. Madras Bul. 67 (1913), pp. 9, pls. 2, figs. 10*).—Twenty-six different pests are noted.

Insects attacking apple, pear, plum, and cherry trees, G. F. WILSON (*London: Roy. Hort. Soc., 1913, pp. 44-72*).—Brief descriptions are given of the more important insect enemies of these trees.

Some insect enemies of the tea plant, C. BERNARD (*Dept. Landb. Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 17 (1912), pp. 21-35, pls. 3*).—The pests here considered are two scales of the family Lecanidinae *Heliothrips hæmorrhoidalis*, *Stauropus alternus*, etc.

Insects on rubber in 1913, A. RUTHERFORD (*Trop. Agr. [Ceylon], 42 (1914), No. 1, pp. 41-44*).—A brief discussion of the more important insect enemies of rubber.

Studies of acute epidemic poliomyelitis, C. KLING and C. LEVADITI (*Ann. Inst. Pasteur, 27 (1913), Nos. 9, pp. 718-749; 10, pp. 839-854, pl. 1, fig. 1; abs. in Rev. Appl. Ent., 1 (1913), Ser. B, No. 11, pp. 216-218*).—In discussing the methods by which this disease may be transmitted in nature a number of pages are devoted to a consideration of the possible transmission of the virus by insects.

Economic importance of the family Sminthuridæ, with notes on an attack of *Bourletiella hortensis* on soy beans, G. H. CORBETT (*Agr. Students' Gaz., n. ser., 16 (1913), No. 4, pp. 128-130, figs. 2*).—*B. hortensis* attacks the under-surface of the cotyledons of soy beans near the edge, where it eats out crescent-shaped holes; it also eats small holes in the upper surface of the seed leaves. Some plants are said to suffer to such an extent that they die. The damage of principal importance is done while the plants are in the seed leaf stage.

On some timbers which resist the attack of termites, KANEHIRA (*Indian Forester*, 40 (1914), No. 1, pp. 23-41).—The author concludes that the factors which make timber termite-proof are the presence in the wood of some substance which has a strong repellant smell or taste; the presence of substances which are poisonous; and extreme hardness.

Combating the locust in the government of Stavropol during the years 1907 to 1912, B. UVAROV (*Bor'ba s Saranchevymi v Stavropol'skoi Gubernii v 1907-1912*. St. Petersburg: Dept. Zeml. Stavropol. Ent. Büro, 1913, pp. 87, pls. 12).—A detailed account of the control measures for locusts, particularly *Stauronotus maroccanus*, employed in Stavropol.

A contribution to the life history and habits of the brown locust (*Diastrammena marmorata*), a greenhouse pest, HERRMANN (*Gartenwelt*, 18 (1914), No. 7, pp. 92-94, fig. 1).—A brief account of this locust as a pest in Silesia, Germany, and the means of combating it.

Froghoppers, J. C. KERSHAW (*Dept. Agr. Trinidad and Tobago*, 1913, Spec. Circs. 4, pp. 3; 5, pp. 6, pl. 1; 6, pp. 7, pls. 2; 7, pp. 4).—The data presented in these circulars have been previously noted from another source (E. S. R., 30, p. 250).

A contribution to the biology of the Coccinellidæ, A. OGLOBLIN (*Russ. Ent. Obozr.*, 13 (1913), No. 1, pp. 27-43, figs. 10).—This paper, which deals with a number of species of lady beetles, includes an account of the biology of two of their parasitic enemies, namely, *Dinocampus terminatus* and *Tetrastichus coccinella*.

African scale insects, L. LINDINGER (*Jahrb. Hamburg. Wiss. Anst.*, 30 (1912), Beiheft 3, pp. 59-100, figs. 9).—This fifth paper deals with the scale insects of German East Africa. See also a previous note (E. S. R., 27, p. 358.)

The Cyrus Thomas collection of Aphididæ, and a tabulation of species mentioned and described in his publications, J. J. DAVIS (*Bul. Ill. State Lab. Nat. Hist.*, 10 (1913), Art. 2, pp. 97-121, pls. 2).—The collection of aphids here considered consists of 73 slides and 176 vials, all of which are in the custody of the Illinois State Laboratory of Natural History. Only species with labels bearing data other than numbers have been determined and are here reported upon.

Notes on European species of the genus *Aphelinus* parasitic upon the plant lice, N. B. KURDJUMOV (*Russ. Ent. Obozr.*, 13 (1913), No. 2, pp. 266-270).—This paper includes a synoptic table of European species of *Aphelinus* with hairy eyes, and descriptions of four species new to science, two of which were reared from *Toxoptera graminum* at the Poltava Experiment Station.

A partial key to the genera of North American Jassoidea, S. E. CRUMB (*Trans. Kans. Acad. Sci.*, 26 (1912), pp. 129-137, figs. 24).—A table is given for the separation of the families of Jassoidea, except Typhlocybidæ; of the subfamilies, except Athysaninæ; and of the genera.

The known species of Japanese Chrysopidæ, H. OKAMOTO (*Trans. Sapporo Nat. Hist. Soc.*, 5 (1913), No. 1, pp. 49-60).—Twelve species of *Chrysopa* are recognized. A bibliography is appended.

Studies on the Mecoptera of Japan, T. MIYAKÉ (*Jour. Col. Agr. Imp. Univ. Tokyo*, 4 (1913), No. 6, pp. 265-400, pls. 10, figs. 6).—A structural and systematic study. Forty species are recorded of which four are new to science. A bibliography of 43 titles is appended.

The Bombidæ of the New World, H. J. FRANKLIN (*Abs. in Canad. Ent.*, 46 (1914), No. 2, pp. 73-76).—This is a review by F. W. L. Sladen of the work previously noted (E. S. R., 30, p. 59).

Carpocapsa pomonella; results of investigations by the Experiment Station of Poltava, I. V. NIKITIN (*Trudy Poltav. Selsk. Khoz. Opytn. Stantsii*, No.

16 (1913), pp. XIII+74, figs. 11; abs. in *Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 10, pp. 364-367).—The first part of the report, devoted to the biology of the codling moth in the government of Poltava, is followed by a discussion of the literature and experiments with the driving spray method. A number of parasites were reared from the larvæ.

The occurrence of the codling moth in Turkestan and the methods employed in combating it, A. F. RADETSKY (*Turkest. Ent. Stantsiia*, 1913, pp. 52, figs. 8; abs. in *Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 10, pp. 367-370).—The codling moth is the most serious insect pest occurring in Russian Turkestan. The small number of parasites attacking it in Turkestan tends to support the view that it has been only recently imported. It is stated that in 1912 *Asco-gaster canifrons* was found infesting 15 per cent of the caterpillars, appearing chiefly in the gardens near Tashkend, its numbers diminishing gradually in proportion to the distance from the town, whereas in the previous year less than 2 per cent of the caterpillars were infested. "In the northern Provinces of Russia there is only one brood of *Laspeyresia pomonella* in the year; in middle and south Russia, two more or less complete broods; while in Russian Turkestan there are three, two complete and one more or less partial, though considerable."

On Escherich's discussion of my work on the wilt disease of the gipsy moth (*Liparis dispar*), W. REIFF (*Naturw. Ztschr. Forst u. Landw.*, 11 (1913), No. 1, pp. 49-54).—A discussion of Escherich's^a review of the work previously noted (*E. S. R.*, 27, p. 659).

Hyponomeuta malinellus, its bionomics and methods of combating it, S. A. MOKRZECKI (*Abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 9, pp. 345-349).—This moth is said to be found everywhere in Russia; while it is not a serious pest in the northern and western Provinces it is a source of very serious injury in the southern and southeastern Provinces. The paper includes a discussion of its natural enemies and means of combating them.

"Barium chlorid when used in 1 per cent or 2 per cent solution (4½ to 6 lbs. of barium in about 27 to 30 gal. of water) is considered to be the most effective. One of its disadvantages is the want of adhesiveness, to obtain which it is recommended by some authors to add potato sirup or a solution of resin in 90 per cent spirit; while the author recommends the addition of soda (about ¼ lb. for the above quantity). The latter transforms some of the barium into BaCO₃, but in his opinion the amount of barium lost in this way is not important, besides it gives the solution a white color, thus facilitating control of the spraying. Another disadvantage is that it burns the leaves of the trees; this, although very serious, can be minimized by careful and rapid spraying. The author states that during 8 years' use of this insecticide under his direction there never was a case of poisoning either of the cattle feeding on the sprinkled grass or of birds."

Nun moth problems, K. ESCHERICH (*Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 2, pp. 65-85).—The subjects discussed in this article include investigations of the value of adhesive bands in combating the nun moth; the number of pine needles consumed by nun moth caterpillars; the food of young caterpillars on pine; the resistance of young caterpillars to cold; the importance of aerostatic hairs of young caterpillars; and nonviable eggs.

"The pink boll worm" (*Gelechia gossypiella*), G. C. DUDGEON (*Agr. Jour. Egypt*, 2 (1913), No. 2, pp. 45-48, pl. 1).—This article relates to *G. gossypiella*, the occurrence of which in Egypt appears to have been overlooked by writers previous to 1911, although specimens have been found commonly in damaged cotton bolls throughout the country for many years.

^a *Naturw. Ztschr. Forst u. Landw.*, 10 (1912), No. 2-3, p. 84.

Phalera bucephala and its importance for the artificial breeding of *Pentarthron* (*Oophthora*) *semblidis* in winter, I. A. PORTCHINSKY (*Trudy Būro Ent. [St. Petersburg.], 10 (1913), No. 4, pp. 16, figs. 8; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 9, pp. 317, 318*).—The author suggests that pupæ of insects hibernating in the pupal stage, such as *P. bucephala*, a moth widely distributed in Russia, or as *P. bucephaloides*, may be used in rearing the chalcidid parasite *Pentarthron semblidis* during the winter for use in combating *Euxoa* (*Agrotis*) *segetum*.

The vine-flower gall midge (*Contarinia viticola*) (*Luxemb. Weinztg., 1 (1913), No. 21, pp. 357, 358; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 9, p. 331*).—This gall midge is said to have occurred in large numbers in vineyards at Schwebsingen (Luxemburg), the damage in 1913 being estimated at one-tenth of the crop.

On certain hematophagous species of the genus *Musca*, with descriptions of two new species, W. S. PATTON and F. W. CRAGG (*Indian Jour. Med. Research, 1 (1913), No. 1, pp. 11–25, pls. 5; abs. in Rev. Appl. Ent., 1 (1913), Ser. B, No. 11, pp. 209, 210*).—It is pointed out that in the genus *Musca*, in which the proboscis is of the type from which the muscid biting flies have evolved, there are certain flies that habitually feed on blood. Though they are confirmed bloodsuckers and have no other food, the proboscis is not adapted for piercing and presents no notable deviations from the type of the genus. "Totally unable to penetrate the skin of the host themselves, they rely on other and better equipped flies to do it for them and feed on the blood and serum which exudes from their bites. For this purpose they associate themselves with the biting muscids, such as *Stomoxys*, *Bdellolarynx*, *Philæatomyia*, and *Lyperosia*, and with the *Tabanidæ*."

The practical importance of this group lies in their probable capacity to transmit disease from one animal to another. Four species studied by the authors in South India, all of which resemble the common house fly superficially, are described, two being new to science.

The migratory habit of house fly larvæ as indicating a favorable remedial measure.—An account of progress, R. H. HUTCHISON (*U. S. Dept. Agr. Bul. 14 (1914), pp. 11*).—"Observations and experiments show that the migratory habit is deeply ingrained and highly characteristic of house fly larvæ. The migratory habit appears in the prepupal stage in response to various internal and external stimuli. Of the external stimuli, moisture is perhaps the most important in determining the direction of their travels and the choice of a place for pupation. The migratory habit is an adaptation of great advantage in that it insures to the issuing adult the easiest and quickest escape. The deep-seated habit offers an important point of attack in the attempt to control the pest.

"Experiments with maggot traps show that 98 or 99 per cent of the total number of larvæ can be made to leave the manure, provided it is kept moist. Even from comparatively dry manure as many as 70 per cent can be destroyed. The development of the maggot trap into an efficient weapon in the warfare against the house fly involves the working out of certain practical points, namely, the size and structure of the trap, the time necessary to keep the manure in the trap to rid it of maggots, the disposal of the larvæ, etc."

A list of 9 references to the literature is appended.

Further reports on flies as carriers of infection (*Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., n. ser., Nos. 66 (1912), pp. 22, pls. 2; 85 (1913), pp. 46, pl. 1, figs. 13*).—Three papers are presented in the fifth of these reports (*E. S. R., 30, p. 658*), namely, *Observations on the Range of Flight of Flies*, by C. G. Hewitt (pp. 1–5); *British Flies which Cause Myiasis in Man*, by E. E. Austen (pp. 5–15); and *An Account of the Bionomics and the Larvæ*

of the Flies *Fannia* (*Homalomyia*) *canicularis* and *F. scalaris* and Their Relation to Myiasis of the Intestinal and Urinary Tracts, by C. G. Hewitt (pp. 15-22). The five papers presented in the sixth report are: *Empusa muscæ* and the Extermination of the House Fly, by H. T. Glissow (pp. 10-14); Hibernation of House Flies, by S. M. Copeman (pp. 14-19); The Range of Flight of *Musca domestica*, by G. H. F. Nuttall, E. Hindle, and G. Merriman (pp. 20-41); Note on the Color Preference of Flies, by E. Hindle (pp. 41-43); and Further Observations on Nonlactose-fermenting Bacilli in Flies, and the Sources from Which They Are Derived, with Special Reference to Morgan's Bacillus, by G. S. Graham-Smith (pp. 43-46).

A new parasite of the house fly (Acarina, Gamasoidea), H. E. EWING (*Ent. News*, 24 (1913), No. 10, pp. 452-456, pl. 1).—*Macrochcles muscæ* n. sp., collected at Ithaca, N. Y., and Corvallis, Oreg., is said to be a true parasite of *Musca domestica*.

Formaldehyde gas not effective upon flies, E. S. TUCKER (*Trans. Kans. Acad. Sci.*, 26 (1912), p. 53).—Formaldehyde gas, generated by 2 lbs. of formalin and $\frac{1}{2}$ lb. of permanganate of potash crystals, in the disinfection of a room containing 1,456 cu. ft. of space, is reported to have had no ill effect upon house flies which were confined in the fumes over night.

The large narcissus bulb fly (*Merodon equestris*), L. CHILDS (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 2, pp. 73-76, figs. 2).—This syrphid pest is said to have frequently been received from Sutter County, Cal., and to have been taken at San Rafael, Cal., where it is reported to live in the bulbs of *Amaryllis*.

Results of work in combating the olive fly in 1912, A. BERLESE (*Bol. Min. Agr., Indus. e Com.* [Rome], Ser. C, 12 (1913), No. 5-7, pp. 7-16).—A summary of the results of the year.

The peach fly, J. C. CASTELLANO (*Gac. Rural* [Buenos Aires], 6 (1913), p. 783; abs. in *Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 9, pp. 310, 311).—The author reports that the peach fly (*Chyliza persicorum*) is the source of much injury to fruit crops in Argentina. It generally appears at the end of February and during March, finding conditions favorable to its development in windfalls or stacked fruit, especially those which have suffered slight damage and present cracks and bruises and where the eggs can be deposited.

Researches on the larval morphology of Diptera of the genus *Phora*, D. KEILIN (*Bul. Sci. France et Belg.*, 45 (1911), No. 1, pp. 27-88, pls. 4, figs. 5).—This detailed report of the author's studies includes work with *Phora bergens-stammi*, *P. rufipes*, *P. ruficornis*, etc., and a review of the literature. A bibliography of 39 titles is appended.

The bionomics of the rat flea, C. STRICKLAND (*Brit. Med. Jour.*, No. 2735 (1913), p. 1160).—These notes relate to the longevity of the adult *Ceratophyllus fasciatus*.

On "Crithidia" fasciculata in hibernating mosquitoes (*Culex pipiens*) and the question of the connection of this parasite with a trypanosome, H. M. WOODCOCK (*Zool. Anz.*, 43 (1914), No. 8, pp. 370-382, figs. 41).—Whether or not this parasite is connected with the trypanosome still remains to be determined.

The boll weevil, G. H. ALFORD (*Chicago* [1914], pp. 31, figs. 18).—A summarized account of the boll weevil and the means by which cotton may be profitably produced in infested territory.

New bark beetles and food plants, Y. NIHSIMA (*Trans. Sapporo Nat. Hist. Soc.*, 5 (1913), No. 1, pp. 1-6).—A number of species of scolytids representing the genera *Hylesinus*, *Polygraphus*, and *Cryphalus* are described as new.

The Meloidæ of Mexico, L. CONRADT (*Bol. Dir. Gen. Agr.* [Mexico], *Rev. Agr.*, 2 (1912), No. 7, pp. 644-649, pls. 2).—A general account of the blister beetles is followed by brief descriptions of nine species found in Mexico.

A new strawberry pest: The metallic flea beetle (*Haltica pagana*), C. FRENCH, JR. (*Jour. Dept. Agr. Victoria*, 11 (1913), No. 10, p. 591).—The author reports that complaints were received from strawberry growers in the districts of Wandin and Evelyn, Victoria, of depredations by the metallic flea beetle, a native insect.

A preliminary report on the sugar beet wireworm, J. E. GRAF (*U. S. Dept. Agr., Bur. Ent. Bul.* 123 (1914), pp. 68, pls. 23, figs. 9).—This, a report of studies of *Limonium californicus* carried on since 1909, describes the manner of injury, the history of the species, the insects associated with it in the destruction of the beet roots in different stages of growth, the number of its food plants, its life history and habits, suggestions as to the methods for its control, etc.

This wireworm has been known in the coast lowlands of southern California for many years, having been more or less destructive to sugar beets during the time they have been grown there, and prior to that time was known as an alfalfa and corn pest, and had caused serious losses in many localities. The Lima bean loss which it occasioned in 1912 is estimated at \$10,000. The sugar beet is killed through the injury to the roots, the wireworm being most injurious while the beets are young. Other wireworms mentioned as associated with it include *Drasterius livens*, *Cardiophorus aeneus*, *C. crinitus*, etc.

This sugar beet wireworm was found quite generally throughout the western half of California, being abundant in the lower sugar beet lands of southern California. The main districts affected by it are those of Ventura, Orange, and Los Angeles counties, which comprise probably the choicest sugar beet land in southern California. A single specimen is said to have been collected in eastern Washington. The other food plants listed are wild beet (*Beta* sp.), potato (*Solanum tuberosum*), corn (all varieties), Johnson grass (*Sorghum halepense*), dock (*Rumex hymenosepalus*), pigweed (*Amaranthus retroflexus*), chrysanthemum, nettle, wild aster, and mustard (*Brassica niger*).

"The life cycle probably covers 4 years. About 1 month each is required for the egg and pupal stages; 7 to 9 months for the adult stage, during the greater part of which the beetle is in hibernation; and about 3 years, or the rest of the time, for the larval stage. Thus far it seems to be impractical to employ remedies against the larvæ. As these live underground and are protected by a thick integument it is difficult to injure them. They also seem able to eat a certain quantity of many poisons and deterrent substances with safety. Plowing in the fall is a fair remedy against the pupæ, but at that time of the year the soil is dry in southern California and is turned up in large clods; consequently many pupæ escape destruction. Much of the injury to the beets may be avoided by early planting, thus giving the roots a good start before the wireworms are doing their most extensive feeding. Clean culture against the adults, by compelling them to seek shelter elsewhere and exposing them to the attacks of their bird enemies, seems to be the most practical remedy found thus far for this insect. The efficiency of this remedy would be increased if fall plowing and early planting were used with it."

Descriptions of thirteen new species of parasitic Hymenoptera and a table to certain species of the genus *Ecphyllus*, S. A. ROHWER (*Proc. U. S. Nat. Mus.*, 45 (1913), pp. 533-540).—Several of the species here described are of economic importance.

A new aphid feeding braconid, N. KURDJUMOV (*Russ. Ent. Obozr.*, 13 (1913), No. 1, pp. 25, 26, fig. 1).—*Diaretus* (*Aphidius*) *obsoletus*, the species here described as new, is an important parasite of two injurious grain aphids, *Brachycolus noxius* and *Toxoptera graminum*.

The larval forms and biology of an entomophagous cynipid (*Eucoila kellini*), D. KEILIN and G. DE LA BAUME PLUVINEL (*Bul. Sci. France et Belg.*,

47 (1913), No. 1, pp. 88-104, pls. 2, figs. 5).—This paper relates to *E. kellini*, a parasite which develops in the general cavity of the larva of *Pegomya winthemi*. It is quite remarkable because of the many larval forms.

A systematic monograph of the chalcidoid Hymenoptera of the subfamily Signiphorinae, A. A. GIRAULT (*Proc. U. S. Nat. Mus.*, 45 (1913), pp. 189-233).—This monograph includes a table for the separation of species of the genus Signiphora, a table of the host relations of the Signiphorinae, and descriptions of 27 species of which 14 are new to science. The species of this subfamily are parasites of scale insects.

An annotated bibliography of 9 titles is appended.

Notes on the chalcidoid Hymenoptera of the family Trichogrammatidae, with description of a new subgenus from Australia, A. A. GIRAULT (*Russ. Ent. Obozr.*, 13 (1913), No. 2, pp. 292-294; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 435, 436).—This paper includes notes on 6 species of parasites of the genus Trichogramma, most of which are of considerable economic importance.

South African "fertile" worker-bees, G. W. ONIONS (*Agr. Jour. Union So. Africa*, 7 (1914), No. 1, pp. 44-46).—In continuation of the article previously noted (*E. S. R.*, 27, p. 865).

On the etiology of foul brood in bees, I. L. SERBINOV (*Selsk. Khoz. i L'sov.*, 242 (1913), July, pp. 367-382; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 11, pp. 441-446).—A report of studies. See also a previous note (*E. S. R.*, 30, p. 161).

Second annual report of the state bee inspector to the governor of the State of Iowa for the year 1913, F. C. PELLETT (*Ann. Rpt. State Bee Insp. Iowa*, 2 (1913), pp. 72, pls. 2, fig. 1).—This report of the work accomplished during the year, particularly as relates to bee diseases, is followed by a number of papers by different authors giving information of value to bee keepers.

Bee keeping industry in Germany, H. L. SPAHR (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 44, p. 717).—"At the end of 1912 there were counted 2,619,891 beehives in Germany, over half of these being in Prussia. Silesia leads the Prussian Provinces with 187,264, and of all the non-Prussian States only Bavaria has more (over 400,000). The Province of Posen counted 122,705."

Synoptic list of ants reported from the Hawaiian Islands, LOUISE GULICK (*Proc. Hawaii. Ent. Soc.*, 2 (1913), No. 5, pp. 306-311).—This is a composite key for the determination of Hawaiian ants, with the collections in which specimens are to be found, and the publications in which the various species are reported from Hawaii.

Injury caused by ants to tobacco, A. SPLENDORE (*Bol. Tec. Cultiv. Tabacchi [Scafati]*, 11 (1912), No. 5, pp. 251-254, pl. 1, fig. 1).—*Messor barbarus*, *Tetramorium coespitum*, and *Formica fusca cinerea* are described as enemies of tobacco.

Annotated list of the Diplopoda and Chilopoda, with a key to the Myriapoda of Kansas, H. GUNTHERP (*Kans. Univ. Sci. Bul.*, 7 (1913), No. 6, pp. 161-182, pl. 1).—This paper includes a bibliography on the Myriapoda consisting of 195 titles.

The rabbit coccidiid *Eimeria stiedae* with a contribution to the knowledge of *E. falciformis*, F. REICH (*Arch. Protistenk.*, 28 (1912), No. 1, pp. 1-42, pls. 4, figs. 13).—A detailed report of biological studies of these protozoan parasites. A bibliography of 68 titles is appended.

Red spider spread by winds, H. P. STABLER (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 12, pp. 777-780, figs. 2).—Investigations made in California are said

to establish the fact that the red spider is blown sufficient distances by the wind to make an infested orchard a menace to orchards within a reasonable distance. Experiments are briefly reported.

Rocky Mountain spotted fever.—A report of its investigation and of work in tick eradication for its control during 1913, L. D. ERICKS (*Pub. Health Rpts. [U. S.], 29 (1914), No. 8, pp. 449-461*).—The author reports upon tick eradication, particularly as relates to domestic animals, including the construction of dipping vats; and also upon the destruction of wild animals, tick surveys, sheep grazing, and the investigation of the geographical distribution of Rocky Mountain spotted fever.

FOODS—HUMAN NUTRITION.

The milling quality of Marquis wheat, C. H. BAILEY (*Minnesota Sta. Bul. 137 (1914), pp. 9-14, fig. 1*).—Comparison was made of the yield of flour, protein content, and bread making quality of middlings flour from samples of Fife, Bluestem, and Marquis wheat grown in the same locality.

The conclusion is reached that "the Marquis wheat samples tested were slightly superior in most respects to the Fife and Bluestem samples raised under the same conditions. A higher yield of total flour was obtained from the Marquis samples and the high-grade or 'middlings flour' contained a higher percentage of protein, absorbed more water in making the dough, and produced loaves of somewhat greater volume. There was comparatively little difference in the color of flour obtained from the two groups of wheat."

The soy bean and its use as a foodstuff (*Konserv. Ztg., 14 (1913), No. 48, pp. 377, 378*).—A brief account of the history, nutritive value, and utilization of the soy bean.

Graphic representation of the value of milk, A. J. J. VANDEVELDE (*Bul. Soc. Chim. Belg., 27 (1913), No. 11, pp. 287-295, figs. 3*).—Believing that the dangers of adulterated milk can be best brought home to the public by graphic representations, the author has worked out and here publishes the mathematical formulas for constructing circular diagrams in which the nutrients and adulterants of milk may be strikingly shown.

Report to the local government board upon the available data in regard to the value of boiled milk as a food for infants and young animals, JANET E. LANE-CLAYTON (*Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., n. ser., No. 63 (1912), pp. 60, figs. 5*).—This report includes an exhaustive summary of the reliable investigations into the relative values of human and other milks, both raw and boiled, for infant feeding, and also detailed reference to a research carried on by Ballin with healthy babies at the Infant Consultation of the Naunyn Strasse in Berlin. Numerous statistics of growth and similar data are given in connection with the Berlin work. The author's summary and conclusions, based on both experimental and clinical data, are as follows:

"There is apparently no serious loss of nutritive value produced by feeding an animal upon boiled milk derived from an animal of the same species. At the same time it must be pointed out that the published evidence on this point is scanty.

"When an animal is fed upon the milk of another species, the milk from which has been found to be suitable for this purpose, such small differences as have been found in the nutritive values of raw and boiled milk have been in favor of boiled milk.

"The milk of the same species has a considerably higher nutritive value for that species than the milk of any other species so far investigated.

"The evidence dealt with throughout this report emphasizes very forcibly the importance of breast feeding for the young of all species and shows the special importance of breast feeding during the early weeks of life.

"Where artificial feeding has been employed in animal experiments, boiled milk of a foreign species has given more satisfactory results than similar milk raw. The Berlin figures dealing with infants fed on boiled cow's milk, give extremely favorable results, and in view of the evidence collected in this report could scarcely be expected to be surpassed had raw cow's milk been used.

"It may be . . . pointed out that the Berlin babies who are artificially fed in connection with the Consultation receive milk of a known excellent quality. The excellence of the results obtained in Berlin are almost certainly largely due to the care and supervision exercised at and through the Consultation."

An extensive bibliography is appended.

The composition of carabao's milk, E. R. DOVEY (*Philippine Jour. Sci., Sect. A*, 8 (1913), No. 3, pp. 151-157).—This study gives detailed analyses of the milk of the carabao, which is described as "with the possible exception of goat's milk, . . . the principal native dairy product in the Philippine Islands." The composition of cheese made from it is also given.

Contribution to the study of "black spots" in frozen meat, M. MÜLLER (*Ztschr. Fleisch u. Milchhyg.*, 24 (1913), No. 5, pp. 97, 98, figs. 2).—The material here described was Norwegian reindeer meat, the mold producing the spots being the same as that found in other frozen meats in England and elsewhere, *Cladosporium herbarum*. References are given to the literature of the subject.

The sandwich and its significance in popular diet, M. RUBNER and SCHULZE (*Arch. Hyg.*, 81 (1913), No. 4-5, pp. 260-271).—In Germany the custom of buying bread spread with butter and some meat preparation to make up the entire meal has become so common among working people in the cities that a systematic study of such sandwiches seemed to the authors desirable. They give analyses and data as to the relative cost of nutrients and energy from sandwiches of different types purchased in the open market, and conclude that these articles provide nutrients in a relatively expensive form. Their use is especially condemned in cases where buying them precludes all use of hot meat at other meals or of a hot beverage with the sandwich.

The significance of finely divided vegetable foods in the economy of the body—a contribution to the study of cellulose digestion, F. W. STRAUCH (*Ztschr. Expt. Path. u. Ther.*, 14 (1913), No. 3, pp. 462-479).—In the extensive digestion experiments on which the author's statements are based the digestibility of fresh vegetables (string beans, green peas, spinach, carrots, and savoy cabbage) prepared in the usual way is compared with that of the same materials reduced to powdered form and then cooked.

Although the relative nutritive values of the ordinary and powdered forms differed somewhat in the various kinds of vegetables used, the coefficients of digestibility of protein and energy from the powdered material were in all cases higher than those from the ordinary preparations. Especially noticeable was the increased resorption of cellulose from the powdered vegetables. It was found possible to include in the daily diet 300 gm. of the dried powders, a much greater amount of the vegetables than could be consumed if taken in the usual way. This is considered of importance for certain dietary regimens, as is also the further fact that even when taken in large quantities or by patients suffering from enteritis, abdominal typhus, fermentative dyspepsia, etc., the cellulose in the powdered vegetables appeared not to irritate the intestinal mucus.

A copper balance on 7 experimental subjects to determine the effect of eating coppered vegetables, C. L. A. SCHMIDT (*Jour. Amer. Chem. Soc.*, 36

(1914), No. 1, pp. 132-136).—The author reports in detail the results of experiments undertaken for Taylor's investigation of the action of coppered vegetables on the health and nutrition of man (E. S. R., 29, p. 762).

When coppered vegetables formed a part of the experimental diet, a distinct retention of copper was noted. "In order to obtain a true balance, an allowance must be made for copper normally ingested in foods. This value can be obtained by assuming that the output of copper in the foreperiod represents the copper ingested during that time. The copper so retained in the body will probably be only slowly eliminated."

Better coffee making—recommendations for dealers and consumers resulting from exhaustive studies which disclosed the importance of fine granulation and the high efficiency of the filtration method, E. ABOEN (*Tea and Coffee Trade Jour.*, 25 (1913), No. 6, pp. 568-574, fig. 1).—This paper, read before the convention of the National Coffee Roasters' Association, November, 1913, discusses the general subject of coffee brewing with special reference to the results of the analysis of coffee infusions prepared by different methods.

Stress is laid on the importance of fresh granulation and accurate methods of measuring materials and temperatures. A mixture of Bogota and Santos coffee, medium roast, in both medium ground and pulverized form, was used in the experiments. Seven tablespoons of coffee (80 gm. of medium and 82 gm. of pulverized coffee) were used to 6 cups of water (750 cc.), which is the usual household allowance. The coffee was prepared in four different ways, namely, boiling, steeping, percolating, and filtration.

Boiled coffee was made by placing medium ground material in cold water, heating it to the boiling point at which it was maintained for 5 minutes, and then adding a little cold water to cause the grounds to settle. Steeped coffee was made in the same way, except that it was settled and poured off directly the boiling point was reached. Finely ground coffee was used for the percolated preparations and the directions provided by the manufacturers of the percolators were followed. Filtered coffee was prepared from finely powdered coffee berries inclosed in a muslin bag over which vigorously boiling water was poured.

The amounts of total solids, tannin, and caffeine in coffee by each method were carefully determined. It was found that the general strength of the brew (amount of total solids present) depended rather on the fineness of granulation than on the length of time which the coffee and water were cooked together. Lengthening the cooking period (as in boiling or percolating) tended to extract more tannin in proportion to caffeine and other bodies on which the desirable flavor seems to depend. In percolators, water far below the boiling point in temperature is sprayed for a considerable period over the coffee, with the result that the flavor is not well extracted though the tannin is, a fact, according to the author, contrary to the claims of many manufacturers. On the whole, filtration was found to produce coffee giving best results as regards both flavor and low tannin content.

The amounts of tannin found in a cup of the various infusions were as follows: Boiled, 2.44 grains; steeped, 2.40 grains; percolated, 2.21 to 2.90 grains; filtered, 0.20 to 0.25 grain. The amounts of caffeine are: Boiled, 2.50 grains; steeped (medium ground), 0.75 grain; steeped (finely ground), 1.75 grains; percolated, 2.75 grains; filtered, 2.50 grains.

The author makes several practical deductions, as follows:

"The use of eggs to settle the coffee is common to boiling and steeping recipes. The effect of the egg . . . is to poach the grounds, which, thus weighted, sink to the bottom. . . . The liquor can be better cleared by straining off and the egg adds a foreign matter to the coffee which is no improvement to flavor. . . .

"The filtration method is the process of relating, in the most efficient way, coffee in its most efficient brewing state, viz, pulverized, to water at its most efficient brewing temperature, boiling. . . . It develops the distinctive characters of various coffees clearly and has a purity to the taste which is strikingly confirmed by the purity shown in the chemical analysis. In using this method emphasis must be placed upon the fact that boiling water, at the full boiling point, 212°, and pulverized coffee are essential. Also that the cloth used must be wet to be kept sweet. . . . Drying the cloth causes decomposition and keeping it in clean, cold water is like putting it in cold storage, preserving it in sweet condition. Pouring the water through more than once obtains a darker liquor but . . . a deteriorated flavor from the addition of tannin and other undesirable elements. The full flavor . . . is extracted by one pouring under efficient conditions."

See also a previous note by Willcox (E. S. R., 30, p. 558).

Monthly bulletin of the dairy and food division of the Pennsylvania Department of Agriculture (*Penn. Dept. Agr., Mo. Bul. Dairy and Food Div., 11 (1913), No. 4-5, pp. 131*).—This bulletin contains the text of the Pennsylvania laws of 1913 relating to food products, notes on food topics from miscellaneous current publications, tabulated analyses of food products made under the direction of the dairy and food commissioner up to June 1, 1913, and miscellaneous data incident to food inspection.

[Report of Congress of Royal Sanitary Institute, Exeter, 1913].—Section C—domestic hygiene (*Jour. Roy. Sanit. Inst., 34 (1913), No. 11, pp. 509-526*).—Among the titles of papers presented are the following: Labor-saving Contrivances, by Miss E. P. Hughes; How to Make the Lessons on the Care and Feeding of Infants of Practical Use to the Babies of To-day, by Miss A. C. Henderson; and The Training of Boys in Cooking after Leaving School, by C. H. Senn.

The popular cook book and family book—a new practical manual of Spanish, French, English, and Mexican cookery, hygiene, and domestic economy (*La Cocinera Poblana o el Libro de las Familias—Novísimo Manual Práctico de Cocina Española, Francesa, Inglesa y Mexicana, Higiene y Economía Doméstica. Mexico, 1913, 8 ed., rev. and enl., pp. 477*).—Besides numerous recipes for dishes common in other countries, this book contains a section devoted to Mexican cooking.

Food materials and condiments—their composition and influence upon health with special reference to the ash constituents, R. BERG (*Die Nahrungs- und Genussmittel—ihre Zusammensetzung und ihr Einfluss auf die Gesundheit, mit besonderer Berücksichtigung der Aschenbestandteile. Dresden, 1913, pp. 60*).—This volume contains the results of original analyses of over 300 common food substances, the proportions of the different mineral constituents present having been determined in each case. In his introduction, the author develops the theory previously noted (E. S. R., 30, p. 562) that to be adequate the diet must furnish sufficient inorganic bases to maintain the alkalinity of the body fluids, and for the practical application of this he believes that such detailed analyses as are here given are essential.

[Rations and equipment for men engaged in fire prevention and control on national forests], S. C. BARTRUM (In *Fire Prevention and Control on National Forests. [Ogden, Utah: U. S. Forest Serv., 1913], pp. 8-10, 18-20, pl. 1*).—Lists are given, among other data, as to the cooking equipment and subsistence supplies required per day for 1 to 30 men. There is also a brief discussion of the commissary, which includes some suggestions for the camp cook and information regarding the purchase of supplies and similar topics.

Modern reforms in nutrition, M. RUEBER (*Arch. Hyg.*, 81 (1913), No. 4-5, pp. 179-259).—The author reviews modern theories of diet, especially those of Chittenden and Hindhede, which point to a lowered protein standard, and gives the reasons for his own belief that in general the Voit standard is the safest for general use.

Diseases due to deficiencies in diet, F. G. HOPKINS (*Lancet [London]*, 1913, II, No. 19, pp. 1309, 1310).—In this address before the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, October 21, 1913, the work of Funk, Holst, and others is discussed, along with the general subject of the relation of deficiencies in diet to such diseases as beri-beri, scurvy, infantile scurvy, and pellagra.

In conclusion reference is made to the author's work with rats infected by sarcoma artificially produced, one group being fed upon bread and milk and the other upon an artificial diet. "In the absence from diet of the substances which promote the growth of normal tissue the sarcoma grew at only one-fourth of its normal rate. Such a result has perhaps no more than an academic importance, but it shows that a neoplasm, like a normal tissue, requires for its growth certain at present unknown substances, which it acquires less readily from the tissues than from the food supply of its host."

Nitrogen metabolism during chronic underfeeding and subsequent realimentation, S. MORGULIS (*Biochem. Bul.*, 3 (1913), No. 9, pp. 74, 75).—This article is a preliminary note on some of the results obtained from experiments with a dog which was subjected to severe underfeeding for many weeks and then put on a rich diet.

The urines were tested with litmus daily. On the third day after the return to the full diet the urine became thoroughly alkaline but remained so for a few days only. The alkalinity appeared to be due to an excess of ammonium carbonate, and the author suggests that "the great influx of phosphates and acid cleavage products of the protein digestion, coupled with a generally impaired condition of the liver and of the whole organism, for that matter, resulted in a rapid elimination of ammonium carbonate before its transformation into urea."

The general physiological transformation of the animal will be discussed in detail in a later publication.

Contribution to the study of nitrogen metabolism—new methods for the determination of urea, ammonia, and amino acids, L. LEMATTE (*Bul. Sci. Pharmacol.*, 20 (1913), Nos. 10, pp. 577-584; 11, pp. 647-659).—In addition to a description of original methods for the determination of the above-mentioned metabolic products by means of phosphotungstic acid, magnesium chlorid, and hypobromid of sodium, the author states the generally received theories of nitrogen metabolism.

Fasting studies.—XII, The ammonia, phosphate, chlorid, and acid excretion of a fasting man, D. W. WILSON and P. B. HAWK (*Jour. Amer. Chem. Soc.*, 36 (1914), No. 1, pp. 137-146, fig. 1).—During a preliminary period of 4 days' duration the subject was given a diet supplying 21.86 gm. of nitrogen. This was followed by a fasting period of 7 days' duration, 1,500 cc. of water being taken per day. A low-proteid period of 4 days' duration followed the fasting period, the daily intake of nitrogen being about 5.23 gm. and the energy value of the diet, 1,800 calories. A final period of 5 days' duration on a high-proteid diet followed, the daily food being increased to the amount eaten during the preliminary period.

The acidity of the urine increased during the fasting period, decreased during the low-proteid period, and in the high-proteid period returned very nearly to the average value noted in the preliminary period. Phosphoric acid excretion decreased in the fasting period, increased somewhat in the low-proteid period,

and in the final period increased still further, approaching the values observed in the preliminary period. The chlorid excretion diminished during the fasting period and the low-proteid period, returning in the high-proteid period practically to the values observed in the preliminary period. These and other factors are discussed.

Fasting studies.—XIII, The output of fecal bacteria as influenced by fasting and by low and high protein intake, N. R. BLATHERWICK and P. B. HAWK (*Jour. Amer. Chem. Soc.*, 36 (1914), No. 1, pp. 147-152).—In connection with the experiment previously noted, the influence of the dietary conditions on fecal bacteria was studied.

According to the author's conclusions, a 7-day fast lowered the daily excretion of fecal bacterial nitrogen by a subject weighing 76 kg. from 1.571 gm. to 0.101 gm. "The percentage of the fecal nitrogen which was present as bacterial nitrogen was decreased from 55.82 per cent to 32.29 per cent as a result of the fast. The percentage of dry bacteria in dry feces was slightly increased.

"The output of bacterial nitrogen and the output of bacterial substance were approximately the same on a low-protein diet as during fasting. With the ingestion of a high-protein diet these values underwent an immediate and pronounced increase.

"The percentage of the fecal nitrogen which was composed of bacterial nitrogen was about the same in the periods of low and high-protein ingestion.

"There was no definite relationship between the excretion of fecal bacteria and that of urinary indican.

"The ingestion of 5.25 gm. of nitrogen after the fast was followed by an excretion of fecal bacteria which was only one-fourteenth as great as when 4 times that amount of nitrogen was ingested before the fast."

The actual weight of the excreted bacterial substance was reduced from 14.336 gm. to 0.920 gm.

Studies on water drinking.—XV, The output of fecal bacteria as influenced by the drinking of distilled water at meal time, N. R. BLATHERWICK and P. B. HAWK (*Biochem. Bul.*, 3 (1913), No. 9, pp. 28-40).—This contribution to a long series of studies on the physiological effects of water drinking (E. S. R., 29, p. 267) is summarized by the authors as follows:

"When 500 cc. of distilled water was added to the usual water ingestion at each meal (100 cc.), a decrease was noted in the amount of bacterial nitrogen excreted daily in the feces. This held true for two subjects. One subject responded more freely to the influence of the water than did the other. When the water ingestion (100 cc.) was increased by 850 cc. per meal, a more pronounced decrease in the daily excretion of bacterial nitrogen was observed. This was more emphasized in the one case than in the other, but was very obvious in both.

"Since the amount of bacterial nitrogen occurring in the feces may, in a way, be considered an index of the utilization of the protein in the food, we are led to conclude that there was a more efficient utilization of the proteins and hence better digestion and absorption when water was taken with meals. In both cases the beneficial results were not confined to the periods of increased water intake, but continued into the periods following.

"Two subjects fed upon a uniform diet for a period of slightly more than 1 month were found to have an average content of 57.54 per cent of bacterial nitrogen in the fecal nitrogen. The average amount of dry bacteria excreted per day was 6.189 gm. The proportion of dry bacteria in dry feces was found to be 29.94 per cent.

"A decreased output of urinary indican was observed to accompany the copious water ingestion. There was, however, no definite relationship between

the values for urinary indican and fecal bacteria nitrogen under all conditions. A definite relationship would probably be accidental."

Studies on water drinking.—XVI, The influence of distilled water drinking with meals upon fat and carbohydrate utilization, N. R. BLATHERWICK and P. B. HAWK (*Jour. Amer. Chem. Soc.*, 36 (1914), No. 1, pp. 152-157).—Two subjects, young men, were maintained upon a uniform diet, and the effect was noted of the copious ingestion of distilled water with meals upon the utilization of the ingested fat and carbohydrate. "The utilization of these nutrients was apparently uninfluenced by the drinking of large volumes of water at meal time."

Studies on water drinking.—XVII, The ammonia output as an index of the stimulation of gastric secretion following water ingestion, F. WELLS and P. B. HAWK (*Jour. Amer. Chem. Soc.*, 36 (1914), No. 1, pp. 158-165).—In experiments with 2 men it was found that the ingestion of water at meal time was accompanied by an increase in the renal excretion of ammonia, directly proportional to the extra volume of water ingested.

"Inasmuch as certain experiments have demonstrated that water stimulates the flow of an acid gastric juice and as certain other experiments have demonstrated that the formation of acid in the body or the introduction of acid from without produces an increase in the urinary ammonia excretion, we feel justified in assuming that the increase in the ammonia excretion observed in our experiments was due directly to the stimulation of gastric secretion by the ingested water.

"The uniform relationship between the water ingestion and the ammonia output might perhaps be considered as indicating that there was an attempt on the part of the gastric cells to maintain a uniform acid concentration."

Calculated on the basis of 100 cc. increasing water ingestion, the increased ammonia excretion was found to be a trifle higher during moderate than during copious water drinking, indicating that after a certain limit in water ingestion is reached the water was less efficient as a stimulating factor in ammonia excretion. That different organisms may respond differently to identical stimuli was indicated by the fact that the ammonia output of one subject was 100 per cent greater than that of the other under uniform conditions.

"That the increase in the ammonia excretion did not arise from intestinal putrefaction was indicated by the finding of lowered indican values during the period of high water ingestion."

Concerning the proteins of muscle juice, F. BOTTAZZI (*Rend. Soc. Chim. Ital.*, 2. ser., 5 (1913), No. 11, pp. 282-285).—Technical studies are here reported with two proteins obtained from the expressed juice of different types of muscular tissue. One, found in solution, is named by the author myoprotein. For the other, held in suspension in the form of minute granules, he retains the classic term myosin. From 35 to 45 per cent, or even more, of the total protein of muscles was found to consist of these two forms. The viscosity, surface tension, and imbibition of the granular preparations were tested.

The extractives of muscle—creatosin, a new base of meat extract, R. KRIMBERG and L. IZRAÏLSKY (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 83 (1913), No. 4, pp. 324-330).—The authors have isolated two previously unknown bases from meat extract. One of these, to which the name creatosin has been given, has, in combination with the gold from auric chlorid used in its separation, the formula $C_{11}H_{28}N_2O_4Au_2Cl_4$. Its detailed characteristics and those of the other, as yet unnamed base, are to be studied further.

Studies in the heat production associated with muscular work, J. S. MACDONALD (*Proc. Roy. Soc. [London]*, ser. B, 87 (1913), No. B 593, pp. 96-112, pl.

1, fig. 1).—This article deals with work done with a previously described calorimeter of the Atwater-Rosa-Benedict type (E. S. R., 27, p. 367). Besides a detailed description of the apparatus, including a bicycle ergometer, the methods and formulas used in calculating results are given at length.

A bicycle ergometer and respiration apparatus for the experimental study of muscular work, A. KROGH (*Skand. Arch. Physiol.*, 30 (1913), No. 4-6, pp. 375-394, figs. 5).—The author describes a bicycle ergometer of special construction for recording and determining muscular work. This was used in connection with a respiration apparatus of the closed-circuit type which will record quantitatively the pulmonary ventilation and the oxygen absorption.

"The CO₂ percentage of the 'alveolar expired air' is not identical with the average CO₂ tension in the alveoli but generally lower.

"The composition of the alveolar expired air can be calculated from the volume and composition of the total expired air when the dead space of the subject has been determined, but the average CO₂ tension in the alveoli can not at present be determined with certainty, especially during muscular work."

ANIMAL PRODUCTION.

Heredity and sex, T. H. MORGAN (*New York, 1913, pp. IX+282, figs. 121*).—The chapters in this book are as follows: The evolution of sex; the mechanism of sex determination; the Mendelian principles of heredity and their bearing on sex; secondary sexual characters and their relation to Darwin's theory of sexual selection; the effects of castration and of transplantation on the secondary sexual characters; gynandromorphism, hermaphroditism, parthenogenesis, and sex; fertility; and special cases of sex inheritance.

Breeding operations, J. FARMER (*Ann. Rpt. Punjab Vet. Col. and Civ. Vet. Dept., 1912-13, pp. 9, 10*).—This relates to the production of cattle, sheep, horses, and donkeys in the Punjab. A statement is given showing the average cost of feed, keep, attendance, etc., of horse, pony, and donkey stallions.

Catalogue of the ungulate mammals in the British Museum (Natural History), R. LYDEKKER (*London, 1913, vol. 1, pp. XVII+249, figs. 55*).—This book deals with a part of the family Bovidae, including cattle, sheep, goats, serows, and related ruminants.

Winter steer feeding, 1912-13, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul. 167 (1913), pp. 3-43*).—A continuation of work previously noted (E. S. R., 28, p. 670).

Three lots of 10 grade Shorthorn steers each, weighing approximately 830 lbs. each and grading as good to choice light feeders were fed during a 180-day period a basal ration of shelled corn and cotton-seed meal, lot 1 receiving clover hay, lot 2 corn silage, and lot 3 clover hay and corn silage as roughage. The addition of silage to a ration of shelled corn, cotton-seed meal, and clover hay decreased the grain consumption 2.38 lbs. and the hay consumption 7.84 lbs. daily per steer, reduced the cost of gain 1.18 cts. per pound, but did not greatly affect the rate of gain on the cattle. The substitution of corn silage for clover hay in the ration reduced the corn consumption 2.25 lbs. daily per head, and the cost of gain 1.26 cts. per pound, but reduced the rate of gain 0.11 lb. daily per steer. Corn silage detracted slightly from the finish of the cattle. Lot 1 returned a profit, including pork produced, of \$10.98 per head; lot 2 of \$18.50 per head; and lot 3 of \$15.41 per head.

Comparing two lots of similar steers receiving a basal ration of shelled corn, cotton-seed meal, and corn silage, it was found that the substitution of oat straw for clover hay did not produce any marked effect on the appetites, gains, or selling value of the cattle but reduced the cost of gain 42 cts. per 100 lbs.

Two lots of 10 2-year-old steers each were fed a ration of shelled corn, oat straw, and corn silage, lot 1 receiving in addition 4 lbs. cotton-seed meal per 1,000 lbs. live weight and lot 2, 2.5 lbs. The latter lot maintained keener appetites, made more rapid gains, produced gains for 0.82 ct. per pound less, and returned a profit, including pork, of \$19.05 per head as compared with \$15.06 per head in lot 1. Cattle acquired the same finish in both lots.

Two lots of steers received a ration of shelled corn, oat straw, and corn silage, lot 1 receiving in addition soy-bean meal and lot 2 cotton-seed meal. It was found that the substitution of the soy-bean meal reduced the quantity of feed eaten and gains made by the cattle, produced gains for 7.89 cts. per pound as compared with 7.74 cts. by the cattle fed cotton-seed meal, but lessened the valuation of the cattle 0.15 ct. per pound. The profit, including pork, from the cattle fed soy-bean meal was \$15.81 per head as compared with \$19.05 per head from cattle fed cotton-seed meal. Soy-bean meal acted as a laxative with full-fed cattle.

Comparing the economy of long and short feeding it was found that cattle fed cotton-seed meal, oat straw, and corn silage gained 2.01 lbs. daily per head for 70 days, while full-fed cattle during the same time gained 2.85 lbs. daily per head. Cattle from which corn was withheld the first 70 days averaged 2.20 lbs. daily per head for 180 days as compared with 2.41 lbs. daily by long-fed cattle. Short-fed cattle increased 0.9 ct. per pound in value in 6 months while long-fed cattle increased 1.2 cts. Short-fed cattle returned \$2.10 per head less profit, including pork, than long-fed cattle.

Feeding of calves on skimmed milk and cassava meal, DECHAMBERE (*Indus. Lait. [Paris], 38 (1913), No. 50, pp. 801-811*).—An account of the feeding of cassava meal as a supplement to a skimmed milk ration for calves, with favorable results.

Rations for fattening western yearling sheep, F. B. MUMFORD, E. A. TROWBRIDGE, and H. HACKEDORN (*Missouri Sta. Bul. 115 (1913), pp. 329-345*).—Seven lots of 20 sheep each, weighing approximately 78 lbs. each, were fed during a 14-week period as follows: Lot 1, shelled corn and timothy hay; lot 2, shelled corn and clover hay; lot 3, shelled corn and linseed oil meal 6:1 (by weight) and clover hay; lot 4, shelled corn and cotton-seed meal 6:1 (by weight) and clover hay; lot 5, shelled corn, corn silage, and clover hay; lot 6, shelled corn and clover hay (self feeder); lot 7, shelled corn and clover hay without shelter. The results of this experiment are summarized in the following table:

Feeding trial with yearling sheep on various rations.

Lot.	Average daily gains per head.	Feed per 100 pounds gain.			Cost of 1 pound gain.	Average shrink per head.	Average cost of feed per head.	Dressing percent- age.	Grade of carcasses.
		Grain.	Silage.	Hay.					
1	<i>Lbs.</i> 0.213	<i>Lbs.</i> 549.28	<i>Lbs.</i>	<i>Lbs.</i> 660.28	<i>Cts.</i> 7.514	<i>Lbs.</i> 5.70	\$1.510	49.6	Fair.
2	.235	524.89	730.73	7.402	5.75	1.730	52.2	Good.
3	.252	490.70	703.43	7.632	6.00	1.890	50.5	Do.
4	.242	511.15	747.57	7.888	4.50	1.873	50.2	Do.
5	.271	455.72	278.61	489.11	6.187	6.50	1.644	49.7	Do.
6	.245	637.42	564.86	7.377	5.20	1.688	49.8	Prime.
7	.200	887.50	617.09	9.424	4.60	1.733	50.6	Good.

It is concluded that under the conditions of the experiment a ration of shelled corn, clover hay, and corn silage was the most economical, and a ration of shelled corn and clover hay second.

It is stated that "as the price of corn and hay increases, it will be found economical to add a nitrogenous supplement. In these trials linseed oil cake was superior to cotton-seed meal. Clover hay proved to be greatly superior to timothy hay as a roughness for fattening western yearling sheep, with shelled corn as the grain ration.

"The lot fed in the open required 6.4 bushels more corn for each 100 lbs. gain than did the lot fed on the same ration in the barn. Feeding sheep in an open lot without shelter from the winter rains and snow is undoubtedly a poor practice."

Fattening western lambs, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul.* 168 (1913), pp. 47-68).—The object of the work reported in this bulletin was to determine the comparative feeding value of the more common roughages of the farm and the advisability of using some concentrated commercial feeding stuff for fattening lambs. Nine lots of 25 choice western lambs weighing approximately 63 lbs. each were fed during a 90-day feeding period with shelled corn and various supplements, with results as shown in the following table:

Summary of lamb-feeding experiments with various supplements to shelled corn.

Lot.	Kind of supplement.	Average daily gain per head.	Feed per pound of gain.					Cost of gain per pound.	Profit per lamb.
			Shelled corn.	Oats.	Cotton-seed meal.	Corn silage.	Clover hay.		
		<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Cents.</i>	
1	Cotton-seed meal, silage.	0.276	3.51	0.15	0.50	9.62	4.87	\$1.77
2	Oats, clover, silage (open lot). .	.308	1.94	2.02	5.43	3.34	6.24	1.58
3	Clover.357	3.42	.11	5.90	6.13	1.76
4	Cotton-seed meal, clover.368	2.91	.11	.42	5.85	6.34	1.86
5	Clover(morning),silage(evening). .	.329	3.57	.12	4.40	3.31	5.35	1.93
6	Clover (morning and evening), silage (morning and evening). .	.337	3.49	.12	4.96	3.11	5.25	2.21
7	Cotton-seed meal (smaller ration), clover, silage.355	3.02	.11	.43	5.46	2.94	5.52	2.05
8	Cotton-seed meal (larger ration), clover, silage.360	2.74	.11	.65	5.39	2.90	5.66	1.97
9	Oats, clover, silage (barn).319	1.88	1.96	5.81	3.18	6.10	1.41

The most profitable rations were those in which shelled corn, clover hay and corn silage were fed. When no silage was fed the rate of gain was satisfactory but the cost of gain was higher than when silage was added to the ration. When silage was fed as the only roughage, the gain was more economical but not as rapid as when clover hay also was fed. The finish of the lambs fed silage alone was also poorer than when both roughages were fed. Oats in the proportion used proved to be too expensive to be used as a partial substitute for corn. Cotton-seed meal increased the rate of gain but did not in all cases add to the finish of the lambs while it always added to the cost of gain. Lambs kept in a barn made as rapid and as economical gains as those in an open shed but did not finish or sell as well.

With the object of determining the influence of shearing during fattening on the appetite, rate of gain, and cost of gain of fattening lambs, two lots each of shorn and unshorn lambs were fed on shelled corn and clover hay, lots 1 and 3 receiving corn silage in addition. The shorn lambs had keener appetites, consumed more feed, and made more rapid gains than unshorn lambs. However, the cost of gain was practically the same. Unshorn lambs yielded heavier fleeces but the shearing had no effect on the profit. Shorn lambs did not require dipping, which was necessary with unshorn lambs.

[On the sheep-carrying capacity of the Roseworthy Agricultural College farm], A. J. PERKINS (*Jour. Dept. Agr. So. Aust.*, 17 (1913), No. 3, pp. 364-390, figs. 4).—This article reports work covering a period of 7 years. The total average acreage of grazing crops on this farm was 149.1 acres and of ordinary pasture 312.2 acres, making a total of 461.3 acres in pasture; and under cultivation 1,072.9 acres, making a total of 1,534.2 acres in total arable-grazing land. The yearly average number of sheep raised was 1,370 or 0.89 sheep per acre of arable-grazing land, and 2.97 sheep per grazing acre.

The feeding stuffs fed to 1,254 head of sheep during 1912-13 (a period largely of hand-feeding) were as follows: Bran 2,766 bu., crushed corn 5,550 lbs., polard 24 bu., hay chaff 11½ tons, straw chaff 19½ tons, baled straw 1,500 lbs., molasses 500 lbs., costing in all £279 5d., or about \$1.11 per head.

The sheep-carrying capacity for the ordinary pasture (fields temporarily out of cultivation) averaged 1.51 head per acre; for stubble fields during 4 months, December to March, 1.55; for fallow grazing, September to December, 0.66; and for the forage crops: Rape, June to January, 2.79; kale, September to January, 5.87; turnips, September to December, 7.27; vetch, September to December, 6.74; peas, September to March, 4.03; lucern, 12 months, 1.35; and sown grasses, consisting of rye grass, cocksfoot, Kentucky blue grass, prairie grass, and sulla, 1.55 head per acre.

The growing and fattening of hogs in the dry lot and on forage crops, E. S. GOOP (*Kentucky Sta. Bul.* 175 (1913), pp. 311-356, figs. 10).—The results of experiments reported in part 1, which treats of the growing and fattening of hogs in the dry lot, demonstrated that with one lot of 39-lb. pigs a gain of but 25 lbs. per head in 196 days was secured on corn alone in a dry lot and at a cost of 17.8 cts. per pound, whereas the same pigs were made to gain 212 lbs. per head in the next 155 days by supplementing the corn meal with shipstuff, green alfalfa, and alfalfa hay at a cost of 5.3 cts. per pound. Forty-pound pigs gained 263 lbs. per head in 223 days at a cost of 5.9 cts. per pound gain by the feeding of middlings, with a small amount of tankage and oil meal for the first 75 days, when the oil meal and tankage were discontinued and corn meal introduced and fed in increasing amounts until at 195 days the pigs were receiving corn meal and middlings 1:1, with corn meal alone for the final 4 weeks. Shipstuff and middlings compared favorably when fed with corn meal to pigs.

Four lots of pigs weighing approximately 64 lbs., fed during a 125-day feeding period as follows: Lot 1 corn meal, lot 2 corn meal, green alfalfa, and alfalfa hay, lot 3 corn meal and soy-bean meal 7:1, and lot 4 corn meal and tankage 7:1, made 86, 142, 139, and 159 lbs. gain per head, costing 6.39, 5.3, 4.79, and 4.8 cts. per pound of gain.

Three lots of 10 hogs each, weighing about 143 lbs. each, and fed 56 days as follows: Lot 1 corn meal alone, lot 2 corn meal and soy-bean meal 10:1, lot 3 corn meal and tankage 14:1, made 76, 84, and 93 lbs. gain per head, costing 5.82, 5.42, and 5.07 cts. per pound of gain, respectively. Comparing the 39-, 64-, and 143-lb. pigs fed corn meal alone it is noted that this becomes a more balanced and economical feed for a hog as he matures, but that in all cases the addition of a nitrogenous supplement such as green alfalfa, alfalfa hay, and soy beans increases the economy of gains.

The average gain made per bushel by all lots of hogs receiving corn meal alone in these dry lot experiments was 8.3 lbs. and by lots receiving a nitrogenous supplement 12.92 lbs.

Runts fed a balanced ration made economical, but small gains. The greatest drawback in the feeding of runts proved to be their slow growing qualities.

Ground wheat, used as a sole ration for pigs averaging 61 lbs. and fed 125 days produced 40 per cent larger gains than corn meal alone fed to a similar lot.

The results of experiments reported in part 2, which deals with the growing and fattening of hogs on forage crops, demonstrated that young, growing cereals such as rye, oats, barley, and wheat contain much more protein and ash and less fiber than the same cereals when more mature and should be classified as nitrogenous instead of carbonaceous roughages. These pastures should be grazed by hogs when the plants measure between 6 and 15 in. in height. As high as 18 lbs. gain per bushel of grain fed has been secured with pigs running in pasture, whereas pigs running on forage crops without grain scarcely maintained their weight. A one-half to three-fourths feed of grain fed during spring, summer, and early fall required the pigs to get the full benefit of the forage crops.

Two lots of 47-lb. pigs fed 155 days as follows: Lot 1 corn meal and rye pasture, lot 2 corn meal and soy beans 6:1 and rye pasture, averaged 168 and 201 lbs. per head, respectively, at the end of the test. Of 2 other lots, one fed corn meal and rye pasture for 147 days averaged 174 lbs., another fed corn meal and tankage 10:1 and rye pasture averaged 214 lbs. In each case greater profits per bushel of corn fed were realized on those lots receiving nitrogenous supplement.

Two lots of 66-lb. pigs fed during 124 days as follows: Lot 1 corn meal, clover, and rye pasture, lot 2 corn meal in a dry lot, averaged 215 and 150 lbs. per head, respectively, at the end of the test. Economy of gains favored the first lot.

Pigs weighing 51 lbs. fed during 166 days on a ration of corn meal and soy-bean meal 9:1 and successive rye, oat, and succotash pastures averaged 222 lbs. at the end of the test and gained 16.47 lbs. for every bushel of grain consumed. It is estimated that each acre pastured was worth \$33.68.

The average gain made per bushel of grain by hogs running on pastures was 15.02 lbs. Estimating pork at 8 cts. per pound the grain fed these hogs realized \$1.20 per bushel, while the average cost was 68.4 cts. per bushel.

Pasture and grain crops for hogs in the Pacific Northwest, B. HUNTER (*U. S. Dept. Agr. Bul. 68 (1914), pp. 27, figs. 9*).—This bulletin deals with crops and systems of cropping with reference to economical pork production in the Pacific Northwest.

The advantages of hogging off crops are considered. The crops generally used for this purpose are wheat, field peas, corn, and barley. The various pasture crops and management methods are discussed, and suggestions offered. It is stated that the utilization of these methods offers an opportunity for profitable pork production in the Pacific Northwest on a much larger scale than at present practiced.

Comparison of pasturing and dry lot feeding methods in swine fattening, M. PORR (*Mitt. Deut. Landw. Gesell., 28 (1913), No. 44, pp. 605-608*).—Two lots of 6 pigs each, weighing approximately 26 kg. per head, were fed during a period of 20 weeks on barley meal, steamed potatoes, fish meal, and skim milk, lot 1 being on pasture and lot 2 in dry lot.

Lot 1 made an average gain per head of 101.7 kg., costing 0.564 mark per kilogram of live weight (6.1 cts. per pound); and lot 2, 104.2 kg., costing 0.551 mark per kilogram. However, during the first 14 weeks the gains and cost of gain were approximately the same, the advantage going to the pigs in the dry lot only after they had reached 100 kg. weight. The bacon measurements of the pastured pigs were 6.8 cm. (2.65 in.) in the forequarter and 5.85 cm. at the loin; of the dry lot-fed, 7.2 and 6.2 cm. The average weight of the stomach of pigs of lot 1 was 617 gm., length 23.8 cm., breadth 12 cm., and volume content 988 cc.; of lot 2, 692 gm., 24.3 cm., 12.7 cm., and 912 cc., respectively. The average weight of the cecum of pigs of lot 1 was 216.7 gm., length 27.7 cm., breadth 13.2

cm., and volume content 2,337 cc.; of lot 2, 201.7 gm., 28.3 cm., 12 cm., and 1,842 cc., respectively.

[Jacks and mules], J. J. HOOPER and W. S. ANDERSON (*Kentucky Sta. Bul.* 176 (1913), pp. 359-409, figs. 27).—Part 1 of this bulletin deals with the principal blood lines of jack stock in Kentucky, the feed, care, and management of jacks and jennets, and methods of judging. Parts 2 and 3 treat of the rearing of mules, the best type of mare for producing mules, the feeding of mules, and market requirements and type.

Part 4 reports feeding experiments in which dried brewers' grains, although not relished by mules, were consumed by them, as well as by horses, in grain mixtures of cracked corn, rolled oats, and bran containing as high as 20 per cent by weight of this feed. During the experiment the animals worked as hard and as satisfactorily as they did before the brewery grains were fed them in such large proportions. The dried brewers' grains proved to be slightly constipating.

In an experiment comparing the relative value of corn and a mixed feed consisting of cracked corn, wheat bran, and oil meal 3:1:1, no noticeable difference was observed in the health, spirit, or weight of the mules. Cotton-seed meal was found to be not so palatable as oil meal. The skin and hair of mules fed the grain mixture were more soft and glossy than those on ear corn, probably due to the oil meal.

It is stated that a great difference was noted in regard to the behavior and efficiency of the 16 mules in the experiment. "The ones that were deep and wide of barrel, large in bone, and closely coupled, showed the least loss of weight on warm days when the work was unusually hard and prolonged. Such mules were ready for their feed and were never ill-tempered. Some of the other mules were long and shallow in body and light in bone, and the last rib did not fit close to the hip. Such mules were fretful; were off feed occasionally, and lost in weight when unusual work was put upon them."

Corn versus oats for work mules, E. A. TROWBRIDGE (*Missouri Sta. Bul.* 114 (1913), pp. 307-325, pl. 1).—This bulletin reports experiments with 2 lots of 2 mules, each fed by the reversal method during a period of 2 years, to determine the relative feeding values of corn and oats.

The lots were maintained in equally good health. The corn-fed mules kept their weight slightly better than did the oat-fed mules. No difference was shown in ability to endure hard work or in spirit. The oat-fed mules required 3 per cent more grain and 1.4 per cent more hay to maintain approximately live weight than did the corn-fed mules. Six per cent more work was performed by the corn-fed than the oat-fed mules. The mules fed corn and mixed timothy and clover hay were maintained 28 per cent more economically than those fed oats and mixed hay, when corn was valued at 50 cts. per bushel, oats at 40 cts. per bushel, and hay at \$10 per ton.

The odd chromosome in the spermatogenesis of the domestic chicken, ALICE M. BOBING and R. PEARL (*Jour. Expt. Zool.*, 16 (1914), No. 1, pp. 53-83, figs. 91).—The investigations of Guyer with Black Langshans, in which he reported the presence of an X-chromosome, are cited, and it is pointed out that if this X-chromosome is assumed to be a sex chromosome the male bird must be heterozygous in regard to sex.

The authors conducted an investigation in which material from the testes of 12 pure Barred Plymouth Rock and cross-bred males was used. From this they conclude that "there is no good observational or statistical evidence of the existence of a sex chromosome in males of domestic chickens of the Barred Plymouth Rock breed. In 11.82 per cent of first spermatocytes and 3.06 per cent of second spermatocytes, there is a piece of chromatin similar to that called an X-chromosome by Guyer in Langshan males. This is not to be regarded as

an X-chromosome in Barred Plymouth Rock males, because: (1) It is present in spermatocytes of both orders; (2) a statistical study of Barred Plymouth Rock cells in comparison with those of the hemipteran *Philænus spumarius* shows that it is present in too few I spermatocytes and in too many II spermatocytes, or vice versa; (3) it is still present in too few cells, if it should be interpreted as one of those rare cases where the odd chromosome divides in either the I or II spermatocyte division; (4) it varies in shape; (5) it varies in size; (6) it varies in number; (7) in no single cells is it of such a shape or size, or in such a position, that it could not readily be interpreted as anything else than an X-chromosome."

The crest of the chicken and duck.—Its cause, formation, and inheritance, F. KRAUTWALD (*Die Haube der Hühner und Enten. Ihre Ursache, Entstehung und Vererbung. Inaug. Diss., Univ. Bern, 1910 pp. 163, figs. 17*).—Studies were made of the peculiarities of feather crested types of domestic poultry. It was found that this condition only occurred in the domesticated breeds, and is an outgrowth of the cuticle which envelops the head. This portion thickens and becomes coarsely vascularized.

The crest is feathered, but the feathers which are of normal make-up are larger and in greater numbers, thus accounting for the characteristic feathered tuft on the crested fowl. With chickens the crest occurs in the frontal region, whereas in ducks it is to be found in the parieto-occipital region. With chickens it takes the form of a congenital internal hydrocephalus, while with ducks it is a congenital occipital encephalocele. In the former case the crest is not completely ossified and is half globular in form, forming a frontal protuberance. In the latter case the skin covers a hole in the lambdoid region. The crest is an external manifestation of a pathological disease which develops in the embryo, and its situation, size, and nature depend upon the situation and degree of the disease. The crest is present in the downy chick and is inherited, the same as other accompanying skull peculiarities. It has become a permanent race characteristic of some breeds of chickens, but is not a permanent feature with the duck.

Egg-laying competitions at Hawkesbury Agricultural College and Experiment Farm, Richmond, New South Wales, D. S. THOMPSON (*Dept. Agr. N. S. Wales, Farmers' Bul. 70 (1913), pp. 19, figs. 11*).—This material has been referred to from another source (E. S. R., 29, p. 472). In addition is noted "the establishment of a new world's record for first-year laying" by a pen of six Indian Runner ducks, laying 1,601 eggs averaging 31 oz. per dozen.

Care and marketing of eggs, compiled by H. E. UPTON (*Dept. Agr. Brit. Columbia Bul. 55 (1913), pp. 15, figs. 5*).—Directions are given for the care, storage, preservation, and grading of eggs, with suggestions on methods of marketing.

DAIRY FARMING—DAIRYING.

Nutrients required for milk production, C. H. ECKLES (*Missouri Sta. Research Bul. 7 (1913), pp. 91-140*).—This bulletin is a continuation of studies previously reported (E. S. R., 26, p. 475).

"The object of the investigation was to secure data regarding the requirements for milk production by cows yielding milk of varying richness. Data are presented giving the feed consumed, with chemical analyses, and of milk produced with analyses for 8 cows for an entire year. The milk of these cows ranged from 3.4 to 6.09 per cent fat. Data of 2 other cows are included for shorter periods. These cows were all fed a ration of practically the same composition. The quantity fed was regulated so as to maintain a uniform

weight. All cows were kept farrow. A maintenance trial was made for 7 cows using the same ration as fed when in milk. A 10-day digestion trial was made for 5 of these when at maximum milk production and again when on maintenance.

"The data bear out the results of others that more energy value is required in the ration for rich milk than for milk lower in fat. The maintenance requirements for the 7 cows showed some variation but was close to Armsby's standard for cows of the same weight.

"The protein fed was in excess of that called for in the standard of Armsby or Haecker but no attempt was made to determine the minimum requirement. When the energy value of the ration, in excess of maintenance, was calculated by the use of 'production value' tables it was found that the cow producing milk with 3.4 per cent fat used 0.245 therms per pound while one with milk averaging 6.09 per cent fat used 0.524 therms per pound.

"When Haecker's maintenance requirement was used and the amount of 'digestible nutrients' calculated by using Henry's tables it was found that 6 cows used more than Haecker's standard and 4 less. When actual maintenance was deducted every cow used nutrients in excess of this standard. The deficiency increased with the richness of the milk. Four Jersey cows required from 23.1 per cent to 55.2 per cent more nutrients than called for by Haecker's standard. This standard is clearly too low for cows with rich milk. According to average digestion coefficients the 5 cows should have digested 70.8 per cent of the ration received during the digestion trial when in milk. The results showed only slight variation with individuals and an average of 65.57 per cent digested. On maintenance the same cows should have digested 66.69 per cent of the ration received, according to average figures, but the results were higher in every case and showed an average of 71.2 per cent.

"A calculation based upon the chemical analyses of the feed and the actual digestion coefficients showed the actual energy value used in the feed per pound of milk was lower than indicated by applying Armsby's 'production value' tables directly to the ration received. The cow producing milk with 3.4 per cent fat actually used only 0.235 therms per pound milk while for 6.09 per cent fat the requirement was 0.442 therms. The total energy required in the feed was slightly less per pound fat produced in the richer milk. However, after subtracting maintenance the energy per pound fat is consistently higher for the richer milk.

"The cheaper production of fat in the richer milk is shown to be due to a smaller maintenance requirement per unit of fat on account of the smaller size of the animals producing the richer milk. The energy value of the milk solids is greater in proportion to the energy value of the feed required with the milk lower in fat. This indicates the production of rich milk requires an increase in feed in excess of the increase in energy value of the milk. The cow is able to utilize energy in her ration to better advantage than is indicated by Armsby's 'production value' tables, which are based upon experiments with mature fattening animals. A tentative standard is given of energy value and protein for cows producing milk from 3 to 6.5 per cent fat."

Feeding sugar-beet pulp to dairy cattle, L. MALPEAUX (*Vie Agr. et Rurale*, 3 (1913), No. 1, pp. 13-16).—In trials comparing the value of ensiled beet pulp and beet fodder for dairy cattle it was observed that the pulp showed superior qualities for milk production, evidently due to its sugar content which develops during the ensilage process. Ensiled pulp of good quality evinced no harmful influence on the quality of the milk, aside from a tendency to increased acidity and a special flavor.

Effect of alkali water on dairy cows, C. LARSEN and D. E. BAILEY (*South Dakota Sta. Bul.* 147 (1913), pp. 300-325).—This bulletin is a continuation of Bulletin 132 (E. S. R., 27, p. 282) and reports experiments with 3 barren cows which were fed a definite ration of grain and silage, and watered during a preliminary 10-day period with normal well water. In the experimental period of 10 days cows 1 and 2 received a strong alkali water and cow 3 soft water.

During the 10-day preliminary period the cows consumed on the average 27.824 lbs. of minerals. Of this 1.9 per cent was in the water, 69.6 per cent in the hay, 10.1 per cent in the grain, 16.2 per cent in the silage, and 2.2 per cent in the salt. Of all the minerals consumed during this period 95.7 per cent was recovered, 5.3 per cent being through the milk, 12.8 per cent through the urine, and 75.6 per cent in the feces.

During the experimental period the cows receiving alkali water consumed an average of 30.7 lbs. minerals, of which 81.1 per cent was recovered, 5.1 per cent being in the milk, 20 per cent in the urine, and 56 per cent in the feces. The cow receiving soft water consumed 24.132 lbs. mineral, of which 82.8 per cent was recovered, 3.9 per cent being in the milk, 13.7 in the urine, and 55.2 per cent in the feces. It is noted that "the increase in ash constituents from the alkali water consisted chiefly of sodium, sulphur, chlorin, and calcium. The alkali water contained about 600 times more sodium, about 30 times more sulphur, about 25 times more chlorin, and about 4 times more calcium than did the normal well water. Potassium, though present only in small quantities, was increased about 15 times over that of the normal well water."

The percentage intake and outgo of each of the ash constituents on the basis of the total consumed minerals for all cows in all periods is as follows: Sulphur, intake 3.8 per cent, outgo 3.4 per cent; chlorin, 3.5 and 2.7; phosphorus 2.7 and 2.6; calcium 4.6 and 4.6; magnesium 3.3 and 3.2; sodium 3.1 and 2.4; potassium 8.6 and 8.8; and silica 49.4 and 44.3 per cent, respectively. Sodium and chlorin constitute the largest part of the ash of perspiration and therefore the determined outgo contained less of these two.

On post-mortem, chemical examinations were made of the kidneys and liver. The composition of the organs of all cows was practically the same, and showed nothing abnormal.

It is concluded from this study that the drinking of alkali water by the cows did not produce what is known as the "alkali disease" or any indication of it. The principal mineral in the alkali water, sodium sulphate, was mostly eliminated through the kidneys. "The urine was increased from 114.6 to 151.4 lbs. during the 10-day periods by reason of drinking alkali water. This increase of urine output took place in spite of a decrease of 148 lbs. in the amount of water drunk during the same period.

"The percentage of ash constituents in the urine is increased by feeding alkali water to the cows. This together with the other above-mentioned facts indicates that the kidneys of cows drinking alkali water have an increased amount of work to perform."

The Fribourger black and white cattle and their introduction in the breeding of the Netherland Black Spotted breed, P. MÜLLER (*Jahrb. Wiss. u. Prakt. Tierzucht*, 8 (1913), pp. 1-87, figs. 20).—After describing the climatic conditions of the canton of Fribourg, Switzerland, and commenting on the adaptability of this section to cattle breeding, the author gives the breed characteristics of the Black and White breed of cattle and lists the principal blood lines, showing wherein the crossing of these cattle on the Netherland breeds has resulted in greater milk yield, increased fat content of milk, and improved milking and fleshing qualities.

What the searchlight of the Swedish Cow Testing Association revealed, J. J. DUNNE (*Hoard's Dairyman*, 46 (1913), No. 17, pp. 489, 495).—Results from the Malmöhus cow testing associations of Sweden are cited which indicate that the relative consumption of fat-free dry matter gradually diminishes as the percentage of fat in the milk increases. For each 0.1 per cent increase of milk fat 1.7 lbs. less feed is consumed in producing 2.2 lbs. of butter fat. It was found that 100 feed units gave an average increase of 10 cts. for each 0.1 per cent of increase in the milk fat percentage, and that there is a corresponding average decrease in the cost of producing 1 lb. of butter of 0.67 ct.

The use of electricity in the continuous sterilization of milk (*Agr. Gaz. N. S. Wales*, 24 (1913), No. 12, pp. 1079, 1080).—It is reported that satisfactory results of a preliminary nature have been attained in the sterilization of milk by use of electricity. Only a short time of exposure was found to be necessary and a high tension current is used. The advantages claimed for the process are that the milk is not heated unduly, that no coagulation occurs, that a continuous stream can be sterilized, and that therefore the method will be available for sterilizing milk on a large scale. In these experiments there was a complete destruction of all colon and allied bacilli and an enormous reduction in bacteria of all kinds. The milk was proved to be unaltered in composition and the enzymes were not destroyed. The taste of the milk was also unaltered and its nutritive value was not diminished.

The experiments also indicate that both natural and artificial contamination with tubercle bacilli can be rendered harmless.

Lobeck's biorisator process, W. FREUND (*Molk. Ztg. [Hildesheim]*, 27 (1913), No. 77, pp. 1489-1491; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 12, pp. 1919, 1920).—The author reports upon a trial of the milk sterilization process recommended by Lobeck.

It was found that "when the biorisator worked normally it did not cause any alteration in the milk as to appearance, color, smell, taste, or capacity of separating cream. The peroxidases also remain unchanged, though catalase and reductase suffer a slight reduction. Coagulation is somewhat delayed, but nowise impaired. The vegetative forms of bacteria, with the exception of individual specially resistant spores of earth and hay bacteria, are killed. All pathogenic germs are certainly destroyed by the biorisator. Biorised milk contains no albumin coagulum and possesses the same fat globules as raw milk. It is considerably superior to raw and pasteurized milk in its keeping qualities."

Quality of the Massachusetts milk supply as shown by the inspection of the state board of health, H. C. LYTGOE (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 11, pp. 922-927).—This investigation was undertaken with special reference to certain enzyme and other reactions which might differentiate raw milk from pasteurized milk and new milk from old milk. After a review of the literature bearing on the subject of enzymes in relation to milk detection the author outlines the investigation as conducted by the Massachusetts state board of health, in which the reductase, peroxidase, and alcohol precipitation reactions were employed. The results of the investigation are summarized as follows:

"It is possible to detect commercial pasteurized milk by the Schardinger reaction but not by the peroxidase reaction. The amount of pasteurized milk on the market is greatest in the large districts. The average quality of the milk is considerably above the legal standard. The average quality of the pasteurized milk is very slightly below that of the raw milk but this does not appear to be due to adulteration. Pasteurized milk shows less fluctuation in composition than raw milk, and the percentage of samples below standard is less of the former.

"Fresh milk will not coagulate with an equal volume of 68 per cent alcohol. Ninety-four per cent of the samples delivered at the laboratory gave reactions for fresh milk; the balance was too old for use as fresh milk."

On the composition of goat's milk, A. STETTER (*Landw. Jahrb.*, 45 (1913), No. 2, pp. 161-178).—This gives numerous analyses of the milk of different breeds of goats and as reported by various investigators.

The progress of dairying in Japan, A. MIYAWAKI (*Hoard's Dairymen*, 46 (1914), No. 25, pp. 749, 759, figs. 2).—The author states that during the past 4 years there has been an increase in the consumption in Japan of condensed milk of 2.66, butter 68.07, and cheese 33.04 per cent. The supply of condensed milk has been largely imported while the butter is principally of home manufacture. The domestic production of butter has trebled in the past 4 years. During 1912 the following importations were made: Condensed milk \$1,044,939.50, butter \$34,915.50, and cheese \$40,331.50. The importations of dairy products are decreasing while the consumption is on the increase.

Amounts are given of several of the noted herds of Ayrshires and Holsteins in Japan.

The butter, cheese, and condensed milk industry (*Thirtieth Census U. S.*, 10 (1910), pp. 357-377).—Of the 8,479 establishments engaged in the industry in 1909, 56.4 per cent reported butter as their product of chief value, 42 per cent cheese, and 1.6 per cent condensed milk. Of the total value of products shown for the combined industry, butter factories contributed 71 per cent, cheese factories 16.1 per cent, and condensed milk factories 12.9 per cent.

The factories of the industry gave employment to 31,506 persons. The value of products reported for the butter, cheese, and condensed milk industry as a whole was nearly 11 times as great in 1909 as in 1879. Comparing 1909 and 1904 statistics it is found that in value of products an increase is shown for each class of establishment, the percentage being 64.5 for the butter factories, 51.9 for the cheese factories, and 72 for the condensed milk factories.

The total production of butter in 1909 was 1,619,415,263 lbs. and of cheese 320,532,181 lbs.

In 1909 Wisconsin was the most important State in the combined industry as measured by the value of products, having displaced New York, which had previously ranked first. Iowa ranked third as regards value of products, Minnesota fourth, and Illinois fifth. The States showing the highest percentage of increase, 1899-1909, were North Dakota 743.4 per cent, Oregon 670, Idaho 662.1, and Missouri 585 per cent.

Individual ownership controls 39.7 per cent, firm 12, corporations 15.5, and cooperative associations 32.7 per cent of the total number of establishments. Individual ownership represents 22.4 per cent, firm 9.8, corporation 41.3, and cooperative associations 26.5 per cent of the total valuation of products. The greater part of the value of the products of the industry was reported by establishments having products valued at \$20,000 or over, these establishments contributing 81 per cent of the total in 1909 as compared with 65.3 per cent in 1904.

Of the 8,479 establishments in the industry in 1909, 12.1 per cent employed no wage earners, 82.5 per cent employed from 1 to 5, and 4 per cent from 6 to 20. The expenses reported for 1909 were distributed as follows: For cost of materials 91.1 per cent, for wages 4.3 per cent; for salaries 1.4; and miscellaneous expenses 3.3 per cent, consisting of amounts paid for advertising, traveling expenses, repairs, taxes, insurance, etc. In 1909 34.3 per cent of the total production of butter reported for the industry was put up in prints and rolls as compared with 21.7 in 1899.

Of the total quantity of cheese made in the factories of the industry 92.3 per cent was full-cream cheese, 3.5 was part-cream cheese, 2.5 skimmed-milk

cheese, and 1.7 per cent various fancy varieties. There has been a marked decrease in the number of cream separators used by the factories, due to their increased use on the farms.

The scientific basis of cheese making and the use of artificial rennet in the manufacture of Emmental cheese, O. ALLEMANN (*Landw. Jahrb. Schweiz*, 27 (1913), No. 5, pp. 325-361; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 12, pp. 1920, 1921).—The author reports as to the advisability of using artificial rennet in the making of Emmental cheese.

It was found that the natural rennet made by the cheese makers and the rennet powder called artificial rennet do not differ much in their action. Aside from the natural rennet being somewhat richer in lactic acid bacteria it is no-wise superior to the artificial product.

Investigation and report on the manufacture of desiccated milk by the Andrews patent process, F. BUCH (*New York*, 1913, pp. 14, figs. 7).—This includes a description of a method of manufacturing milk powder and the necessary equipment for a milk-powder plant, an itemized account of probable expenses and profits from such a plant, and a list of some milk-powder products.

VETERINARY MEDICINE.

Annual report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, for the year 1912-13, A. SMITH and P. J. KERR (*Ann. Rpt. Bengal Vet. Col. and Civ. Vet. Dept.*, 1912-13, pp. 4+10+VII+2+3).—This, the usual annual report, includes the reports of the epizootic diseases department in Calcutta and its vicinity and the Raymond Research Laboratory.

Regulations adopted by the live stock sanitary board and the live stock sanitary law of Alabama (*Opelika, Ala.*, 1912, pp. 30, figs. 3).—The regulations relating to Alabama are here brought together in convenient form. Illustrated plans for dipping vats with directions for their construction and a brief discussion of the arsenical and oil emulsion dips are appended.

Provisions of the agricultural law relating to diseases of domestic animals, 1913 (*N. Y. Dept. Agr. Circ.* 89 (1913), pp. 1917-1932).—The text of the law is presented.

Some immunity reactions of edestin.—III, The biological reactions of the vegetable proteins, B. WHITE and O. T. AVERY (*Jour. Infect. Diseases*, 13 (1913), No. 1, pp. 103-123).—A continuation of work previously noted (*E. S. R.*, 30, p. 680).

"Crystallized preparations of edestin from hemp seed and gliadin from wheat flour were used, and were specially prepared for anaphylactic experiments by Dr. Thomas B. Osborne. They were dissolved in water with the addition of the smallest possible amount of sodium hydrate necessary to effect solution.

"Edestin, even in small amounts, agglutinates washed red blood corpuscles of the sheep and of man. Both edestin-immune serum and peptone completely inhibit this action under the conditions noted. Gliadin, in the amounts used, exerts no agglutinating action. The serum of a rabbit which has been immunized with edestin contains a precipitating antibody for edestin, but none for gliadin in at least twice the concentration, giving a positive reaction with edestin. Edestin, in the presence of edestin immune serum, when both are used in nonanticomplementary and nonhemolytic amounts, completely binds complement. Gliadin, in the presence of edestin immune serum, fails to bind complement.

"[As to the] sensitizing dose, 0.0000001 gm. edestin, injected intraperitoneally, may be considered as the minimum sensitizing dose. Guinea pigs sensitized

with this amount react fatally when a sufficient amount of edestin (0.05 gm.) is injected intravenously after the proper interval. When the sensitizing dose is $\frac{1}{16}$ to 5 mg. the intravenous injection of $\frac{1}{4}$ mg. produces typical anaphylactic death in from 2 to 6 minutes. Pigs sensitized to edestin fail to react to intravenous injections of gliadin, or the globulins from squash seed, the castor bean, or the hazelnut. Two animals reacted positively, one fatally, when given an intravenous injection of flaxseed globulin. The fatal dose of flaxseed globulin was, however, 40 to 120 times the minimum fatal intoxicating dose of edestin. Guinea pigs born of a mother sensitized with edestin while pregnant inherit this sensitiveness but possess it to a somewhat less degree than does the mother.

"The intraperitoneal injection of edestin-immune rabbit serum passively sensitizes the guinea pig; 0.05 to 0.1 cc. of two such sera tested rendered guinea pigs sufficiently sensitive to react fatally to an intravenous injection of edestin on the following day. The degree of sensitiveness passively conferred appears to be somewhat greater than that induced by active sensitization. When edestin is hydrolyzed by an alcoholic solution of sodium hydrate according to the method of Vaughan, a substance is formed which produces a fatal intoxication in the guinea pig, apparently identical with true anaphylactic shock. The intravenous injection of one part of this poison to 40,000 parts of guinea pig by weight constitutes the minimum fatal dose.

"When suitable amounts of edestin and edestin-immune serum are allowed to remain in contact for a given length of time, a precipitate is formed which, when washed with salt solution and mixed with fresh guinea pig complement and incubated at body temperature, yields a substance or substances which, when injected into a guinea pig intravenously, produces a fatal intoxication, apparently identical in every way with the anaphylactic reaction. Fresh complement, when allowed to act under similar conditions with edestin alone, yields no poisonous substance. From edestin, therefore, by the action of immune serum and complement, under the experimental conditions noted, a toxic product is obtained which seems to correspond to the anaphylatoxin of Friedberger."

The action of alcohol in different concentrations upon the antigenic properties of horse meat protein, H. KODAMA (*Ztschr. Hyg. u. Infektionskrankh.*, 74 (1913), No. 1, pp. 30-44; *abs. in Chem. Abs.*, 7 (1913), No. 13, p. 2244).—Alcohol, when added to horse-meat extracts or solid tissues, destroys the antigenic properties of the protein in a few days. The greatest destruction is noted when the concentration of alcohol in the mixture is from 60 to 70 per cent. The anaphylactic reaction is the first to disappear, then the complement fixation, and finally the precipitin reaction.

The use of formalinized blood corpuscles in the complement fixation test, W. PFEILER and KÄTE LOSSOW (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 5 (1913), No. 4, pp. 276-280).—The tests show that for practical purposes it is best to treat the red blood corpuscles in an unwashed state with formaldehyde, and then to keep them on ice or at room temperature. When required for use they should be washed.

Bacterial vaccine therapy: Its indications and limitations, L. HEKTOEN ET AL. (*Jour. Amer. Med. Assoc.*, 60 (1913), Nos. 17, pp. 1298, 1299; 18, pp. 1360, 1361; 19, pp. 1459-1461; 20, pp. 1539-1541; 21, pp. 1621, 1622; 22, pp. 1704, 1705; 23, pp. 1791, 1792; 24, pp. 1880, 1881; 25, pp. 1955, 1956; 26, pp. 2046, 2047).—This deals with the evolution of bacterial therapy, its pitfalls, theoretical considerations (varieties of immunity, antibodies, antigens, factors of active immunity, opsonic index, etc.); classification of bacterial vaccines (autogenous, stock, mixed stock and its use, and objections to autogenous vaccines); inocula-

tion technique and dosage; commercial stock vaccines, untoward effects of vaccines, and misleading therapeutic claims regarding them; dangerous recommendations, technical objections to marketed stock vaccines (possibility of dangerous contaminations, etc.); mixed vaccines a makeshift (incompatibilities, etc.); ideal vaccine therapy (commercial vaccines of single species alone desirable; preparing mixed vaccines, etc.); and vaccines of single species (staphylococcus and streptococcus vaccines).

A portion of the ninth and practically all of the tenth section of the article deals with infections peculiar to man.

A method for standardizing bacterial vaccines, J. G. HOPKINS (*Jour. Amer. Med. Assoc.*, 60 (1913), No. 21, pp. 1615-1617, fig. 1).—The method consists in measuring the volume of the moist bacteria after centrifugalization in a tube with a graduated capillary tip.

The importance of crows and foxes in the distribution of anthrax, F. MOLLET (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 70 (1913), No. 1-2, pp. 19-23; *abs. in Rev. Bact.*, 3 (1913), No. 4, p. 80).—In experiments in which anthrax bacilli and their spores were fed to crows (*Corvus corone*) and foxes (*Canis vulpes*) it was found that the bacilli could be cultivated from the feces when anthrax spores had been ingested. The experimental animals did not appear to be affected in any way.

Experimental insect transmission of anthrax, M. B. MITZMAIN (*Pub. Health Rpts. [U. S.]*, 29 (1914), No. 2, pp. 75-77).—In this preliminary note the author records three experiments in which both *Stomoxys calcitrans* and *Tabanus striatus* conveyed anthrax infection directly from infected to healthy guinea pigs.

Typical organisms were found in the feces of horse flies at various intervals up to 48 hours from the time the infected animal was bitten. "The accumulated deposits of 3 tabanids, 2 to 3 days after the infective bites, were injected in a saline suspension into a healthy guinea pig, which died of typical anthrax 4 days later. . . . The feces of the stable fly were likewise found to be infected up to 24 hours after obtaining blood from a sick animal. A nearly pure culture of anthrax was obtained from the droppings of 2 flies fed 24 hours previously on infected material."

In regard to the limits of infection in flies, an appended note states that since this article was written it has again been proved that *S. calcitrans* will transmit anthrax, and that bacilli may be found in the feces 14 to 17 days, inclusive, and positive cultures obtained from the stomach for 19 days. In the case of *T. striatus*, which sucked blood direct from the infected animal, bacilli were found in the feces for a period of 10 days.

In regard to combating anthrax, with particular reference to the examination of the vaccines, W. RICKMANN and K. JOSEPH (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), No. 7, pp. 402-438, figs. 7).—The results show that it is possible to determine the value of an anthrax immune serum with both rabbits and guinea pigs. From a technical standpoint, however, the guinea pig alone is suited for the exact titration of the serum. Anthrax serum (Höchst) was found to have a pronounced curative property for laboratory animals and the domesticated animals. For this purpose it seems advisable to give the first intravenous injection in conjunction with a subcutaneous injection of the serum. Smaller injections are then given subcutaneously as long as no typical fall in temperature is noted. In establishments where an epizootic is present the serum treatment is the only one which can be recommended.

The serovaccination method (serovaccine) elaborated by the authors has given good results both in laboratory experiments and in practice. The uniformity of serovaccine is dependent upon the method used in its preparation.

The diagnosis of echinococcus disease in man with the intradermal reaction, T. CASONI (*Folia Clin. Chim. e Microsc.*, 4 (1912), No. 3, pp. 5-16, figs. 2; abs. in *Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1057).—For the test the hydatid fluid of living bovines is employed, and the reaction manifests itself by the appearance of erythematous spots with edematous infiltration of the skin, itching, and a local increase in temperature. The tests were made with 25 individuals, 8 of which were affected with echinococcus cysts and the remainder with various other diseases.

The melostagmin reaction for detecting echinococcus disease in bovines and sheep, P. SILVA (*Tierärztl. Zentbl.*, 35 (1912), No. 27, pp. 416, 417; abs. in *Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1062).—The sera from 4 cows and 8 sheep which were infected with echinococcus disease gave a positive reaction with an alcoholic extract made from the membranes of the cyst or the cystic fluid. Ten sound cows and sheep gave negative reactions.

Complement fixation in Malta fever, A. MISSIROLI (*Policlin.*, Sez. Med., 19 (1912), pp. 414-421; abs. in *Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1119).—While it was established that specific amboceptors were present in the sera of subjects affected with Malta fever, it was found, however, that the sera behaved differently as regards complement fixation with different *melitensis* strains. The test in its present form is thought to possess no real value as a diagnostic agent for this disease.

Cultivation of malarial plasmodia in vitro, C. C. BASS (*Amer. Jour. Trop. Diseases and Prev. Med.*, 1 (1914), No. 8, pp. 546-564, pls. 4).—A summarized account of the subject with references to the literature. See also a previous note (*E. S. R.*, 28, p. 179).

Further cultivation of the malarial parasites and of piroplasms (*Piroplasma canis*) in vitro, H. ZIEMANN (*Arch. Schiffs u. Tropen Hyg.*, 18 (1914), No. 3, pp. 77-93, fig. 1).—This paper reports upon studies conducted in continuation of those previously noted (*E. S. R.*, 30, p. 481).

Epidemic poliomyelitis and distemper of dogs, R. H. PIERSON (*Jour. Amer. Med. Assoc.*, 62 (1914), No. 9, pp. 678-680, figs. 2).—The author reports upon investigations made of a small epidemic of poliomyelitis among Indians of fishing villages in central Alaska near the town of Tanana on the Yukon River. In all there were a few more than 30 cases of the disease. The epidemic among human subjects was preceded by an epidemic of distemper among dogs, the symptoms manifested by the dogs being similar to those shown by the human subjects.

The author thinks that the theory that the disease is common to dogs and human beings fits so well the experience in epidemics which have taken place in different parts of the United States that it is well worth further investigation.

Information on the animal trypanosome diseases of German East Africa, H. BRAUN and E. TEICHMANN (*Arch. Schiffs u. Tropen Hyg.*, 18 (1914), Beiheft 1, pp. 39, pl. 1, figs. 2).—This report of the authors' studies includes a colored plate of the several trypanosomes concerned.

Trypanosomes found in wild *Glossina morsitans*, A. KINGHORN and W. YORKE (*Ann. Trop. Med. and Par.*, 7 (1913), No. 2, pp. 239-244).—"Trypanosoma *rhodesiensis*? *T. inotum*, and *T. pecorum* are transmitted by *G. morsitans* in nature, and were obtained by feeding wild, freshly caught *G. morsitans* on healthy monkeys."

Wild game as a trypanosome reservoir in the Uganda Protectorate, with some criticisms on the current methods of diagnosing these Protozoa, H. L. DUKE (*Arch. Protistenk.*, 32 (1914), No. 3, pp. 393-406).—The experiments here reported show that "the continued infectivity to monkeys of the wild *Glossina*

palpalis on the islands of Lake Victoria may be explained by the fact that the situtunga on these islands are acting as a reservoir to *Trypanosoma gambiense*. The continued infectivity of the mainland flies to *T. gambiense* may probably be explained on a similar hypothesis—not only situtunga but the other species of game also (i. e., water buck, bush buck, duiker, and reedbuck, buffalo, etc.) acting as a reservoir. No positive evidence can be adduced from the above experiments to show that hippopotamus can serve as a reservoir. The continued infectivity of the lake shore flies to *T. vivax* and *T. uniforme* is also due to the antelope which served as a reservoir for these trypanosomes.

"It has been shown that the buffalo and the hyena as well as the various antelope may carry trypanosomes which are pathogenic to cattle without themselves showing any signs of disease. Presumably elephant and the various Felidae may also act as a reservoir, and possibly many of the smaller mammals which abound throughout the country but which are seldom seen by man. In a state of nature such creatures, even if mainly nocturnal in their habits, must at times meet with tsetse, and however improbable it may seem that they may serve as a reservoir for the pathogenic trypanosomes, they must be borne in mind in considering the present problem. Until more is known concerning the habits of Glossina, it is justifiable to suspect any animal with which it may come in contact."

On the morphology and the retention of the trypanosomes found by P. Behn in German cattle, C. BONGER (*Ztschr. Hyg. u. Infektionskrankh.*, 75 (1913), No. 1, pp. 101-117, pl. 1, fig. 1; *abs. in Rev. Bact.*, 3 (1913), No. 4, p. 86).—The author believes the German trypanosome to be very closely allied to, if not identical with, *Trypanosoma theileri*. A bibliography of 20 titles is appended.

Some chemical conditions influencing acid-proofness and nonacid-proofness in a saprophytic culture of *Bacillus tuberculosis*, W. B. WHERRY (*Jour. Infect. Diseases*, 13 (1913), No. 1, pp. 144-154).—"During a study of the growth of a saprophytic culture of *B. tuberculosis* in various synthetic media, it was observed that the morphology varied from minute coccoid bodies to short or long, thick or thin, straight or curved rods which were or were not acid-proof according to the conditions of growth. The culture could be rendered nonacid-proof by continual growth under conditions unfavorable to the synthesis of fats. The culture could synthesize fatty bodies rendering it acid-proof when such substances as acetates were the source of carbon and nitrogen; or from various ammonium salts and propyl alcohol; or from NH_4Cl and mannit; or from NH_4Cl and levulose; or from glycerin and glucose in the presence of peptone.

"Various carbohydrates and the alcohol mannit were not attacked in the absence of phosphates. Various phosphates other than KH_2PO_4 , favored fermentation, but acid-proof rods developed only in cultures containing NH_4Cl and levulose in the presence of potassium dihydrogen phosphate, calcium phosphate (secondary and tertiary), sodium biphosphate (primary), sodium pyrophosphate, and to a lesser degree in the presence of sodium phosphate (secondary). Under the conditions of the experiments the sporelike bodies produced were killed by heating to 60°C . for 30 minutes. That is, they were killed unless they require some very special conditions for germination.

"From the results of vital staining it seems reasonable to conclude that the chemical composition of these artificially produced acid-proof tubercle bacilli is different from that of virulent tubercle bacilli."

The branched forms of the tubercle bacillus, and immunity to tuberculosis, S. G. DIXON (*Jour. Amer. Med. Assoc.*, 60 (1913), No. 13, pp. 993-995, figs. 4).—After discussing the facts in regard to the involution forms of tubercle bacilli, especially the branched forms which are low in protective wax content, it is

suggested that such nonacid-fast forms of bacteria might possibly be used for immunizing purposes. They are also supposed to be less toxic than the other strains. By injecting living branched forms it is possible to produce a marked degree of immunity in guinea pigs. These facts are in accordance with the results obtained in clinical work with a watery extract and the suspension of degreased tubercle bacilli, which has been previously reported by another author.

A comparative study in regard to the resisting powers of the goat and guinea pig against the tuberculosis bacillus, G. SBARAGLINI (*Riv. Crit. Clin. Med.*, 13 (1912), No. 3, pp. 37-41; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1109).—The experiments were made with a very susceptible guinea pig and a less susceptible goat and included the determination of the opsonic index and agglutination. The leucocytes of the goat destroyed the bacteria very readily in vivo and in vitro. In the guinea pig the leucocytic reaction was tardy and of a low order. The same differences were noted in the agglutination.

The blood findings in tuberculosis, LYDIA RABINOWITSCH (*Berlin. Klin. Wchnschr.*, 50 (1913), No. 3, pp. 110-112; *abs. in Jour. Amer. Med. Assoc.*, 60 (1913), No. 9, p. 703).—"A report [of a] research which apparently confirms the assumptions of Virchow and Orth, published 22 years ago, to the effect that an injection of tuberculin is liable to rout out the tubercle bacilli from their nests and drive them into the blood. In the numerous accounts that have been published in the last few months of the findings of the bacilli in the blood it is not stated whether the patients had been taking tuberculin or not. Bacmeister has recently stated that inoculation of animals with the blood from 15 tuberculous patients gave constantly negative results, but after 4 of the patients had been given a diagnostic injection of tuberculin with a distinct local reaction, then the inoculation of animals all gave positive results. He added that there can be no doubt that virulent bacilli had been driven out of the diseased organ into the circulating blood by the injection of tuberculin, and remarks that this is a pretty serious thing."

La pataleta: Some observations on a disease of stock observed in the southern territories of Argentina, J. M. QUEVEDO (*Bol. Min. Agr. [Buenos Aires]*, 14 (1912), No. 9, pp. 1030-1040, figs. 5).—This paper describes an affection of equines, bovines, and ovines which has been observed since 1907 in Patagonia. The disease resembles the enzootic paraplegia of sheep, previously described by the author (*E. S. R.*, 28, p. 183), but differs in the species and age of the animals attacked, the latter only occurring in adult sheep.

Scrapie, an obscure disease of sheep, S. STOCKMAN (*Jour. Compar. Path. and Ther.*, 26 (1913), No. 4, pp. 317-327).—This article relates to a fatal disease of sheep, which occurs on the borders of England and Scotland and is increasing in prevalence, but about which but little has been known until recently. It is characterized by intense itching, locomotor troubles, emaciation, and death in from 3 to 4 months. As a rule the active symptoms are not met with except in sheep over 18 months of age. When the disease is established on a farm the losses from it often amount annually to 4 per cent of the sheep and may be as high as 19 per cent. No remedy has been found up to the present time but experiments with curative treatment are under way.

Sheep dipping tanks.—An improved design for a circular tank, B. G. ENSLIN and W. S. H. CLEGHORNE (*Agr. Jour. Union So. Africa*, 7 (1914), No. 1, pp. 25-29, figs. 10).—A description and plan are given of a circular dipping tank.

The preparation of caustic soda and sulphur dip, A. D. SHILSTON (*Agr. Jour. Union So. Africa*, 6 (1913), No. 5, pp. 746-749).—"With proper care in

mixing, the chemical reaction between sulphur and caustic soda is practically complete, so that little or no free caustic soda remains in the liquid. Nonobservance of the directions may, however, lead to the production of a fluid containing considerable amounts of free caustic soda and little dissolved sulphur. Boiling the correctly mixed fluid causes after a short time the precipitation of sulphur, but unless continued for an hour or more this is not sufficient to weaken the fluid seriously, and in any case free caustic soda is not liberated by the process. Boiling the ingredients for 10 minutes is sufficient to complete the chemical reaction, even when the mixing has been improperly carried out, and is the surest means of producing a fluid of uniform composition. When the mixture is going to be boiled, it is not necessary to employ boiling water for mixing the sulphur paste, and more water may be added than when the mixture is not boiled."

The camel and its diseases: A review, J. M. KOWALEWSKI (*Jour. Méd. Vét. et Zootech.*, 63 (1912), Aug., pp. 462-466; Sept., pp. 540-549; Oct., pp. 600-613).—The first part of this work (pp. 462-464) deals briefly with the races of the camel in Russia; the second part with their diseases, including a preliminary study of bubonic plague in camels made at the bacteriological laboratory at Astrakhan.

Electrocardiogram of horse, A. D. WALLER (*Jour. Physiol.*, 47 (1914), No. 6, pp. XXXII-XXXIV, figs. 2).—The author having correlated the electrocardiogram with the pressure changes finds "that in the horse, as in man, the first and second ventricular waves V_I and V_{II} (or according to the now prevalent rubric R and T) correspond very nearly with the beginning and end of the ventricular systole, or with the first and second sounds."

Investigations of the lateral cartilages (Cartilagine unguæ) of horses, M. LUNGWITZ and H. ERLE (*Anat. Anz.*, 43 (1913), No. 12-13, pp. 313-326, figs. 8; abs. in *Jour. Roy. Micros. Soc.* [London], 1913, No. 3, p. 280).—The authors' histological studies of the lateral cartilages led to the conclusion that they are always fibrous and not hyaline.

Researches on the ascarid toxin, M. WEINBERG and A. JULIEN (*Hyg. Viande et Lait*, 7 (1913), No. 5, pp. 225-244, figs. 2).—This is a report of investigations conducted in continuation of those previously noted (*E. S. R.*, 25, p. 590).

The instillation of the ascarid (*Ascaris megalocephala*) toxin into the horse's eye produced a local reaction characterized by edema of the eyelids, congestion of the conjunctiva, and lachrymation in 168, or about 66 per cent, of the 256 horses tested. Sometimes the local reaction was accompanied by more serious symptoms, including dyspœna, diarrhea, and profuse perspiration. The ocular reaction appears quickly and lasts from 12 to 24 hours, but the general symptoms, at times very threatening, disappear in 2 or 3 hours. The action of the toxin following the instillation of the perienteric liquid is variable, some worms having strong toxins while others have weak ones. The ocular reaction may even be produced by the toxin at a dilution of 1:5,000. The perienteric liquid is dependent for its action upon a series of active substances. According to Flury's investigations^a its poisonous action is due to aldehydes, fatty acids, and their esters. The toxin is thermostable, passes the Chamberlain filter, and is partially dissolved in alcohol and ether. Its volatile products are also toxic.

Horses infested by ascarids are immunized by degrees against the action of toxins secreted by these parasites. The instillation of perienteric liquid usually does not produce an ocular reaction in them. The serum of infested horses contains specific antibodies capable of neutralizing in vitro very weak dilutions of the ascarid toxin. Among the other intestinal parasites of the horse the

^aArch. Expt. Path. u. Pharmkol., 67 (1912), No. 4-5, pp. 275-392.

sclerostome alone secretes a substance capable of producing an ocular reaction; this reaction is less frequent and weaker than that produced by the perienteric liquid of the ascarid.

Locust poison. W. G. COOK (*Vet. Alumni Quart. [Ohio State Univ.], 1 (1913), No. 2, pp. 54, 55*).—A report of the fatal poisoning of 2 horses, caused by chewing the inner bark of a locust tree (*Robinia pseudacacia*) to which they had been hitched.

The vector of mal de caderas. F. W. URICH (*Proc. Agr. Soc. Trinidad and Tobago, 1914, No. 1, pp. 8, 9*).—In his discussion of the probable intermediate agent in the transmission in Trinidad of this disease of the horse, the author states that the stable fly (*Stomoxys calcitrans*) occurs all over the island. A hematophagous bug, *Triatoma geniculatus*, which may possibly convey the trypanosome, is said to occur in Trinidad as well as in Brazil.

The occurrence of distomes in the intestine of the dog at Montpellier. G. R. BLANC and H. HEDIN (*Compt. Rend. Soc. Biol. [Paris], 74 (1913), No. 15, pp. 884, 885; abs. in Rev. Bact., 3 (1913), No. 4, p. 87*).—The authors report the discovery of fluke parasites in the intestines of 2 of 50 dogs examined in Montpellier. The parasite, which is very small, appears to be a new species and has been named *Echinostoma piriforme*.

Controlling chicken pox, sore head, or contagious epithelioma by vaccination. F. B. HADLEY and B. A. BEACH (*Proc. Amer. Vet. Med. Assoc., 50 (1913), pp. 704-712, pl. 1; Amer. Vet. Rev., 44 (1913), No. 3, pp. 330-339, fig. 1*).—Chicken pox and roup are believed to be the same disease manifesting itself in different forms. Repeated success was attained in transmitting the disease by subcutaneous inoculation of a few drops of a normal salt solution of the virus made by macerating the comb and wattle tissue from birds showing well-marked lesions of sore head, although the disease could not be produced by this method every time.

The incubation period varied from 3 to 20 days and diphtheritic membranes frequently appeared on the nasal, oral, and conjunctival surfaces when the virus was placed on them or injected subcutaneously. The involved epithelium of the comb showed an increase in the size of the epithelial cells, which appeared to contain inclusions and inflammatory changes in the deeper layers.

In the treatment of the disease autogenous vaccines gave very satisfactory results. "Best results were obtained by two doses. The vaccine is especially applicable in large commercial and valuable breeding flocks when used before pathological changes become marked. The vaccination treatment for chicken pox was most valuable when used as a preventive, where it was effective in fully 98 per cent of the cases. One attack conferred immunity. The immunity which resulted from the vaccination is estimated to be effective for 1½ to 2 years.

"It was found impossible to transmit the disease at every attempt due to certain peculiarities of the virus and the fowls. When the attempts were successful the disease ran a benign course, as it also did in the few cases in which it made an appearance after vaccination. Experiments to show that chicken pox is caused by a filterable virus resulted negatively.

"Although the identity of chicken pox and roup has not been definitely proved, the similarity of these diseases is so great that it seems possible to control roup by vaccination."

Edema of the wattles of fowls due to an organism of the Pasteurella group. H. R. SEDDON (*Vet. Jour., 70 (1914), No. 463, pp. 24-34, figs. 5*).—This paper has been summarized by the author as follows:

"The breed affected in the cases under review was White Leghorn, but probably any breed with large wattles would be liable to the complaint. It has

been produced experimentally in other breeds of fowls. In natural cases or following scarification and rubbing in of culture the first symptom noticed is the rapid swelling of the wattles, due to the presence of edema, which may also be found exuding from the surface. Septicemia and death occurs in a certain percentage of cases. The disease usually runs a chronic course with subsequent replacing of the fluid by fibrous tissue, formation of nodules of necrotic material, and results in the wattle assuming a crinkled appearance. The cause is a *Pasteurella*, apparently identical with that causing chicken cholera. It produces a septicemia with early death on inoculation into pigeons and rabbits. Entrance is probably through wounds obtained while scratching, fighting, etc. Immunity is attained in chronic cases, which, however, are probably capable of acting as 'carriers.' "

The cases amenable to treatment by "cropping" of the wattles and the adoption of sanitary measures of benefit in suppression of the disease are also discussed.

Enteritis of birds caused by *Bacillus paratyphosus* B, R. MANNINGER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 70 (1913), No. 1-2, pp. 12-14; abs. in Rev. Bact., 3 (1913), No. 4, p. 78*).—An epidemic of enteritis among song birds of the finch tribe in the zoological gardens at Budapest was found to be caused by *B. paratyphosus* B which is considered to be very closely allied to *B. psittacosis*.

Some external parasites of poultry, H. E. EWING (*Oreg. Agr. Col. Bul. 92 (1913), pp. 16, figs. 12*).—A brief popular account of the more important external parasites of poultry.

RURAL ENGINEERING.

Engineering principles applied to farm irrigation, A. L. HARRIS (*Engin. News. 70 (1913), No. 24, pp. 1172-1175, figs. 5*).—This article calls attention to the present day importance of cooperation between the agricultural engineer and the irrigation farmer. It describes the systematic arrangement and equipment of a farmer's irrigation ditches, taking up topographic survey and map; soil survey; design and equipment of water conducting system to withstand erosion and so far as possible to be self-cleaning; and improvements to reduce labor, facilitate the operation of irrigating and effect economy of water, time, and land area.

Flow of water in pipes, E. A. MORITZ (*Engin. Rec., 68 (1913), No. 24, pp. 667-670, fig. 1*).—The author presents a new formula and describes its applications to flow in wood-stave, cast iron, riveted steel, and concrete conduits. For wood-stave pipe the formula is $Q = 1.35 D^3 \cdot H^{0.555}$ and is the same for cast iron and riveted steel, except that coefficients of 1.31 and 1.18 respectively are used in place of the coefficient 1.35. Q equals the discharge in second-feet, D equals the diameter of pipe in feet, and H is the friction loss per 1,000 feet of pipe.

Wet-mix concrete pipe are classed with the cast iron pipe, and dry-mix concrete pipe with the riveted steel pipe. Comparisons of this formula with those in standard use show the results to be nearly identical, and it is stated that the cumbersome use of many coefficients is eliminated.

Irrigation practice, J. S. WELCH (*Idaho Sta. Bul. 78 (1914), pp. 27, figs. 9*).—This bulletin points out briefly the character of work in irrigation practice at the station and reports the results so far obtained by irrigation investigations, and the results of soil management experiments in so far as they relate to the duty of water. A summary of results indicates the following:

"In the preparation of new lands for irrigation farming careful attention should be paid to proper leveling. . . . Alfalfa should be irrigated by the corru-

gation method during its first season, after which flooding between borders is more satisfactory in most cases. In the production of alfalfa hay seven or eight irrigations should be given in a three crop season, totaling about $2\frac{1}{4}$ acre-feet per acre. The moisture supplied by winter and spring precipitation is usually sufficient to carry winter wheat to the booting stage, after which one or two irrigations totaling less than one acre-foot per acre should be given. Flooding between borders is a desirable method of application.

"In the irrigation of spring wheat, oats, and barley care should be taken to have a comparatively high soil moisture content at the jointing, booting, and soft dough stages. The water can be applied to advantage by flooding between borders," using in all $1\frac{1}{2}$ to $1\frac{3}{4}$ acre-feet per acre in about 4 applications. The irrigation of potatoes should commence about the time the tubers begin to form. During the next 5 or 6 weeks about 4 irrigations should be given, applying in all about $1\frac{3}{4}$ acre-feet per acre, the early irrigations being followed by cultivation.

"The improvement of sagebrush lands by the addition of barnyard manure and by the growing of leguminous crops will result in a saving of water. . . . The growing of diversified crops is one of the most efficient means by which the duty of water can be increased."

Irrigation in South Africa, A. C. CARBARNES (*Agr. Jour. Union So. Africa*, 6 (1913), No. 4, pp. 638-644).—Practical irrigating methods are described and suggestions given for the use of the beginner in laying out a field for irrigation.

Report and plans for reclamation of lands subject to overflow in the Embarrass River Valley, J. A. HARMAN (*Ill. Geol. Survey Bul.* 25 (1913), pp. 61, pls. 9).—The plans included in this report, propose (1) straightening the crooked channel; (2) building adequate levees to allow floodwater movement without its covering farm land; (3) excavating ditches for the diversion of hillside water; and (4) installing pumping stations to care for the drainage of each unit area during times of flood. The estimated average cost of the work is \$30 per acre, the benefit derived from such improvements being considered to exceed the cost.

Testing drain tile and sewer pipe, M. SCHUYLER (*Engin. Rec.*, 68 (1913), No. 25, pp. 695-697, figs. 3).—An analysis of theoretical considerations relative to the testing of drain tile led to the following conclusions:

All failures of tile are the results of overstressing in tension some generally elemental section. When tile vary from piece to piece as much as 100 per cent a demand for a sensitivity of 10 per cent in the load indicating details would seem sufficient. This could be obtained readily and accurately by a spring dynamometer and Ames dial gage. Since only the more perfect of the cement tiles allow a continuous contact between a rigid platen and the tile, either a plaster bearing or some flexible platen such as sand or water should be used. Tile should be tested individually to determine their ability to sustain the loading superimposed by particular ditch conditions. This procedure would necessitate a portable machine and considerable labor, but would amply repay this effort under extreme conditions.

Drilling as a test for concrete, C. S. DUKE (*Engin. Rec.*, 68 (1913), No. 24, pp. 670, 671, figs. 3).—Data and results are given of experiments made to determine the relation between compression strength and speed of boring in concrete. It is stated that "all things being equal the rate of boring concrete would in a general way vary inversely as the compressive strength," but it is concluded that the drilling furnished a very unreliable criterion as to the character of the concrete on account of the variation in the age of the concrete, the personal

equation of the drillers, and the condition of the drill as to sharpness and dullness.

[Standard tests for brick] (*Brick and Clay Rec.*, 43 (1913), No. 3, pp. 272, 273).—Specifications are given, as suggested by the American Society for Testing Materials, which cover transverse, freezing, compression, and absorption tests and classification and sampling for vitrified and hard burned brick and common brick first and common brick second.

The part played by water in macadam road construction, W. G. FEARN-SIDES (*Surveyor*, 44 (1913), No. 1141, pp. 808-811, fig. 1).—The author deals with the limitations of water as an essential constituent in macadam road construction, taking up the chemical disintegration of road stones, physical characteristics of water in roads, behavior of water-bound materials, the tensile and crushing strength of road stone, potholes, foundation stone, subcrust dew, and frost. The conclusions point to the importance of surface and under drainage for roads, and to the fact that each and every road aggregate has a characteristic optimum water proportion for efficient service.

Reinforced concrete bridges, F. RINGS (*New York*, 1913, pp. XI+183, pls. 8, figs. 365).—In this book it has been attempted to collect as much data and material as possible relating to the design of reinforced concrete bridges, and to publish the most important features and facts with which the designer of bridges should be acquainted. The subject matter is presented under the following chapters: Bending moments, stresses, and strains; loads on bridges and external stresses; culverts, covering, tunnel, etc.; beam bridges; calculation of girder bridges with examples; design of arched bridges and abutments, with examples; theory of the arch; and formulas, notes, schedules, and useful information.

Use of wind motors in Egypt, DELACROIX-MARSY (*Bul. Union Agr. Égypte*, 10 (1912), No. 91, pp. 269-278; 11 (1913), No. 97, pp. 142-153).—This article discusses the generalities of the problem of the utilization of wind power in Egypt and its possibilities, particularly for pumping for both drainage and irrigation. Results of irrigation experiments led to the conclusion that this method may be employed in the spring in Upper Egypt in places where the wind is strong and blows daily, and that under certain conditions wind power may be applicable for drainage pumping in Lower Egypt.

Central [electric] station practice of Windsor, Vt. (*Elect. World*, 62 (1913), No. 23, pp. 1153-1159, figs. 20).—This article describes the development of a small electrical central station system, supplying electricity to a manufacturing and rural community in the upper Connecticut Valley. Several typical private installations supplied with power by this system are illustrated and described.

Lighting costs 15 cts. per kilowatt hour up to an energy consumption of 20 kilowatt hours per month, with a reduction in steps down to 6 cts. minimum for over 350 kilowatt hours. Motor service prices have a base rate of 7½ cts. per kilowatt hour, discounted by 10 per cent steps up to 50 per cent off for users of 2,000 kilowatt hours per month. The minimum charge for both lighting and motor service is \$1 per month.

Experiments in electro-culture near Dayton, Ohio, H. G. DORSEY (*Elect. World*, 62 (1913), No. 24, pp. 1217, 1218, fig. 1).—In experiments conducted to determine the effect of electricity and artificial illumination on growth of vegetation, the plats subjected to high-frequency electrification showed a greater increase in yield than any of the others. Ruby light ranged second for radishes, while violet light was second for lettuce. The edible portion of lettuce grown on the high-frequency plat was 75 per cent greater than under natural conditions. Tests of high-frequency electrification on a larger scale showed an increase in all garden crops except beans and peas.

Motor plow test of the German Agricultural Society, B. LICHTENBERGER (*Deut. Landw. Presse*, 40 (1913), No. 86, pp. 1027-1029, figs. 11).—Nine different outfits were entered in this contest, 1 wire cable 2-engine outfit, 5 outfits with the tractor and plow separate, and 3 with combined tractor and plow. In the main competitive tests fuel, water, and lubrication consumption; speed and efficiency of operation; width and depth of furrow, etc., were determined. These were followed by a duration test under different conditions of soil and atmosphere.

All the outfits but one finished the duration test in good condition, but many defects were noted in each. Two of the engines in systems having the engine and plow separate did very good work in stony ground with moldboard plows, especially the so-called "caterpillar" tractor. Likewise another such system with moldboard plows and also a cable-drawn balance plow did good work under poor conditions of soil.

It is concluded from the results obtained that each of the three systems has a practical application for certain conditions.

A year of mechanical cultivation, R. BARENNE and H. DE MAESAY (*Bul. Soc. Agr. France*, 1913, Nov. 1, pp. 230-239).—This reports a year's results of mechanical cultivation operations in the domain of Bégûère, which indicate the practicability, in conditions analogous to those of Bégûère, of introducing mechanical power to replace the scarce and poor manual labor.

Test of a refrigerating plant, J. REZEK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 2 (1913), No. 1, pp. 1-16, pl. 1).—A sulphur dioxide refrigerating plant for dairies is described and diagrammatically illustrated. Tests of this plant indicate its refrigerating and ice-forming capacities and its efficiency for the direct cooling of milk.

A test of a cooling apparatus for cooling fresh milk in milk cans, R. EICHLOFF (*Ztschr. Landw. Kammer Braunschweig*, 82 (1913), No. 30, pp. 364-366, figs. 3).—A simple milk cooling apparatus is described consisting of two parts, a tank opening at the bottom into an open ended pipe and a second but smaller tank opening at the bottom into a closed end pipe with a star section. The first part is placed on the second part, fitting loosely, and the whole is placed on a can of milk so that the two tanks are outside and the pipes extend to the bottom of the can. The upper tank is filled with water which flows down the pipe, out into the pipe with star cross section, back up into the second tank, and over the outside of the milk can, thus effecting a double cooling inside and outside.

Tests of this apparatus indicate its simplicity and practicability for the rapid cooling of milk for immediate commercial purposes, and show that three times filling of the upper tank with water results in a suitable temperature of the milk in about 30 minutes.

[**Farm house heating**], **A. A. POTTER** (*Country Gent.*, 78 (1913), No. 46, pp. 1676-1678, figs. 3).—This article describes and diagrammatically illustrates simple systems of hot air, hot water, and steam heating for country homes, and points out the chief factors to be considered in the selection, installation, and manipulation of a system.

Ozone water-purifying apparatus (*Elect. World*, 62 (1913), No. 24, pp. 1231, 1232, fig. 1).—Two types of small ozone water purifiers are described, one for use in residences and the other for factories. A filter is a necessary adjunct of the ozonizing apparatus in places where the water is turbid.

Water, its properties and practical uses.—XX, [The septic tank system], F. W. TOWER (*Dom. Engin.*, 65 (1913), No. 9, pp. 270, 271, figs. 2).—This article presents the theory of operation of a septic tank in concise form and

gives suggestions for the installation of a residential plant consisting of three chambers, a grit chamber, a settling compartment, and a discharge chamber. Final disposal by discharging into an underground pipe absorption system is recommended where possible, but when the soil is wet, heavy, or of a clay nature, it is suggested that the contents of the discharge chamber be siphoned into an underground filter of broken stone and gravel and from there to a second filter of sand. From this it is necessary to pump the filtered water at stated intervals.

Water, its properties and practical uses.—**XXI.** [Installation of house and subsoil drains and cellar drainers], F. W. TOWER (*Dom. Engin.*, 65 (1913), No. 12, pp. 368-371, figs. 3).—This article deals with the design and installation of house sewer plumbing and diagrammatically illustrates and describes subsoil drains and cellar drainers. A velocity of 275 ft. per minute is considered desirable in house drains in order to clear all drains of solids and refuse.

Septic tanks and sewage disposal (*Dom. Engin.*, 65 (1913), No. 11, pp. 330-334, figs. 16).—The subject of sewage disposal is reviewed and the operation of septic tanks and disposal systems briefly described.

School hygiene, F. B. DRESSLAR (*New York*, 1913, pp. XI+369, figs. 51).—The topics discussed in this book cover nearly the whole field of school sanitation and the health of school children, among the more prominent being those dealing with the location, construction, and equipment of school buildings, common physical defects and need of medical inspection of school children, and recent pedagogical theories regarding play, home work, etc. While many of the statements refer chiefly to city schools, many others apply equally to rural schools, and the water supply and sanitary equipment of the latter are especially discussed.

Experiments in school room ventilation with reduced air supply through individual ducts, F. BASS (*Heating and Ventilating Mag.*, 10 (1913), No. 8, pp. 16-24, figs. 11; *Amer. Jour. Pub. Health*, 3 (1913), No. 11, pp. 1135-1137).—The results of an experiment on the recirculation of air and the use of ozone in school ventilation indicate that in an average school recirculation and renewal of the air for three weeks is an esthetic and hygienic possibility and will effect heating economy.

Some preliminary studies in air washing and its results, G. C. and M. C. WHIPPLE (*Amer. Jour. Pub. Health*, 3 (1913), No. 11, pp. 1138-1153).—Experiments in air washing showed that about two-thirds of the suspended particles, including dust, bacteria, and molds, were removed by this process. It is believed that air washing is one of the vital elements of ventilation in localities where a clean supply of air is difficult to obtain, and that the recirculation of such air is deserving of serious consideration from the standpoint of heating economy, especially in cold climates.

Concrete garbage burners (*Irrig. Age*, 29 (1913), No. 2, p. 52, figs. 2).—Two small concrete garbage burners for use on the farm are illustrated and briefly described.

RURAL ECONOMICS.

The census methods of the future.—Agricultural statistics, E. D. DURAND (*Quart. Pubs. Amer. Statis. Assoc.*, n. ser., 13 (1913), No. 104, pp. 568-573).—The author concludes that it seems desirable in the future to employ the rural mail carrier to collect federal agricultural statistics; to obtain annually by actual enumeration the numbers of domestic animals and the acreage and production of the principal crops; to distribute part at least of those inquiries which need to be asked only at decennial intervals among the individual years of the

decade; and to rely upon data from selected farms for most information regarding values.

[The manufacturing industry and its relation to agriculture] (*Thirteenth Census U. S., 10 (1910)*, pp. 319-434, 469-508, 573-585, 677-694, figs. 12).—This volume of the census contains data for 1869-1909 showing the number of establishments, persons engaged in the industry, primary horse power, capital, expenses, values of products, and value added by manufacturing, materials used, and products manufactured for the following industries: Agricultural implements, butter, cheese, and condensed milk, canning and preserving, flour mill and gristmill, glucose and starch, rice cleaning and polishing, sugar, lumber, fertilizers, turpentine, and rosin.

The agricultural implement industry (*Thirteenth Census U. S., 10 (1910)*, pp. 321-330).—According to the census returns between 1889 and 1909 the number of establishments manufacturing agricultural implements decreased from 910 to 640, but the number of wage earners increased from 38,827 to 50,551, the horse power used from 50,395 to 100,601, and the value of products from \$81,271,651 to \$146,329,268. Among the statistical tables shown is one giving the number of principal kinds of implements manufactured in 1899, 1904, and 1909.

The Oregon farmer (*Portland, Oreg., 1913*, pp. 136, figs. 19, pl. 1).—This book, prepared by the Oregon State Immigration Commission, contains a series of articles relating to agriculture in Oregon, based partially upon original inquiries and partially upon other official records, and describes the live stock, dairy, and poultry industries, soil, climate, fruit and farm crops, farm finance, and rural life of the State.

[Brazil's trade in agricultural products], P. DE TOLEDO (*Introduc. Relat. Min. Agr., Indus., e Com., Brazil, 1913*, pp. XCII).—This report gives statistics relating to immigration and the principal agricultural products imported and exported.

Statistics of the production of cereals and legumes (*Estadística de la Producción de Cereales y Leguminosas. Madrid: Junta Consult. Agron., 1913*, pp. [28]).—This report contains data relating to the area and production of cereals and legumes by regions and provinces of Spain for 1913, and by regions only for 1909 to 1913.

[Agricultural and pastoral statistics for Queensland], T. SHACKEL (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1912-13*, pp. 126-184, pls. 15).—Data are given relating to the principal classes of live stock and the areas and production of the principal crops for 1903 to 1912, and to dairy products for 1908 to 1912.

British rural life and labor, F. G. HEATH (*London, 1911*, pp. XI+348, fig. 1).—The author discusses the general system of labor; extras, piece work, and allowances in kind; and earnings, food, and migration of agricultural laborers in England, Wales, Scotland, and Ireland. Tables are included showing the earnings and the quantity and value of the food consumed and describes some typical conditions.

Report on the decline in the agricultural population of Great Britain, 1881-1906, R. H. REW (*Bd. Agr. and Fisheries [London], Rpt. Decline in Agr. Pop. Gr. Brit., 1881-1906*, pp. 143, pl. 1, figs. 2).—This report contains abstracts from the replies of 248 agricultural correspondents regarding the changes that have taken place in the agricultural population since 1901, the causes of the decline in agricultural population, and the extent to which changes in the systems of farming have affected the demand for laborers. Statistical tables are included for 1881, 1891, and 1901, showing by counties the number of the various types of agricultural workers, the area of arable land and permanent pasture

and the number of cattle and sheep, and for 1885, 1895, and 1905 the number of agricultural holdings.

General outline of the new Russian land reforms (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel.*, 4 (1913), No. 2, pp. 119-134, pl. 1; 5 (1914), No. 1, pp. 132-160, pl. 1).—This article outlines the history of the land reform movement beginning with 1861, the work of the land commissions appointed under the law of 1906, the extent of the readjustment of peasant holdings, and the influence of the Peasants' Land Bank, in financing the movement. An extensive bibliography is included.

The national forward-to-the-land league ([*Boston, Mass.*, 1913], pp. 1-8).—According to this report the purpose of this league is to enlist public-spirited capitalists in investing in agricultural land contiguous to their own city at a low rate of interest and to equip it for occupancy to relieve the congestion in the great cities. It also aims to educate those placed on the land in intensive cultivation methods.

Agricultural credit.—Land mortgage or long-term credit (*U. S. Senate*, 68. Cong., 2. Sess., Doc. 380 (1914), pp. 73).—This document contains a description and analysis of long-term credit as found in European countries with modifications deemed necessary to meet conditions in the United States. It also contains an interpretation of the legislation suggested and a statement of the considerations which have influenced the United States Commission on Rural Credits in submitting a bill for a national farm land bank system which is appended.

The agricultural credit in the kingdom of Bohemia, A. BLAŽEK (*Prague*, 1913, pp. 3, pl. 1).—From a study of the history and present condition of agricultural credit in Bohemia the author concludes that in the future there should be a closer organization through the union of the Raiffeisen cooperations, the district farmers' loaning banks, and the Mortgage Bank.

The land credit question in German East Africa, RHODE (*Verhandl. Kolon. Wirtschaftl. Kom.*, No. 1 (1913), pp. 39-47).—This article describes the organization of the Southwest African Land Credit Association and its relation to the agricultural development of the colony, and contains comments by Hupfeld and Schwarze.

The need of community cooperation in crop production and marketing, H. L. BOLLEY (*N. Dak. Farmer*, 15 (1914), No. 8, pp. 4-7).—The author concludes that the farmers in certain large commercial crop-growing regions should so handle their crops that each particular region may become a center of production for a certain particular variety of a crop.

Bureau of marketing, E. J. WATSON (*Ann. Rpt. Comr. Agr., Com. and Indus. S. C.*, 10 (1913), pp. 224-240).—By listing in a weekly paper persons having farm products for sale and those desiring to purchase the commissioner is endeavoring to find a market for the farm products of his State without any other medium of exchange.

Forest insurance in Norway (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel.*, 4 (1913), No. 9, pp. 47-55).—This article contains a discussion of the extent and value of the forests in Norway, the fire preventive measures used, and the organization of the Norwegian Mutual Forest Fire Insurance Society, and reports the results of the first year of its work.

A Norwegian forest fire insurance association, J. A. LARSEN (*Forestry Quart.*, 11 (1913), No. 4, pp. 525, 526).—An account of the organization and results of this work, also noted above.

The insurance of cattle in France, L. HÉRONNAUX (*Jour. Soc. Roy. Cent. Agr. Belg.*, 61 (1913), No. 2, pp. 42-49).—The author discusses the influence of local conditions in fixing rates and the relationship of the local associations to

the central organization and gives a brief summary of the growth of this type of insurance in France.

A system of farm cost accounting, C. E. LADD (*U. S. Dept. Agr., Farmers' Bul.* 572 (1914), pp. 15).—This bulletin aims to give a description of a system of farm accounting which has been used for three years in the State of New York on 53 farms under widely different conditions, and describes in detail the methods employed in making the inventory, the financial record, the working record, the classification of farm products and seed, and in closing the account at the end of the year. Each phase of the accounting is illustrated with a sample entry.

Children or cotton? L. W. HINE (*Survey*, 31 (1914), No. 19, pp. 589-592, figs. 7).—The author in this article discusses the employment of child labor in cotton picking and the influence upon the child and suggests possible methods that might be used to prevent its use.

The American Red Cross rural nursing service (*Washington, D. C.*, [1913], pp. 8).—This service is organized to enable rural communities to have the advantage of a trained nurse similar to that found in the cities. This pamphlet contains suggestions for the organization of a local nursing association, and outlines the duties, by-laws, methods of financing, and regulations for rural nurses.

AGRICULTURAL EDUCATION.

The Development Fund and its distribution, R. HART-SYNNOT (*Jour. Farmers' Club* [London], 1912, Nov., pp. 103-126).—This paper concerning the establishment of the Development Fund and the plans under which it is being distributed was read before the Farmers' Club and discussed by its members.

Memorandum as to the constitution of the advisory councils for agricultural education in England and of the agricultural council for Wales (*London: Bd. Agr. and Fisheries*, 1913, pp. 11).—Detailed information is given in regard to the form of constitution agreed upon for each of the 9 advisory councils for England and 1 in Wales to promote the organization of the different forms of agricultural instruction which are not carried on within an agricultural education institution.

Higher education in agriculture, veterinary science, forestry, and horticulture in Prussia (*Jour. Bd. Agr.* [London], 20 (1913), No. 9, pp. 761-773).—This article gives a description and outlines the history of the development of various university and other agricultural institutes, and explains how the students of the higher agricultural institutions are recruited in view of the fact that there is no educational ladder connecting them with the lower branches of agricultural education.

Agricultural instruction under the chamber of agriculture (*Jahresber. Landw. Kammer Stettin, Prov. Pommern*, 1912, pp. 77, 78, 83, 84, 96-109).—This is a report on the work in 1912-13 of the agricultural and home economics schools in general and individually, and on special courses and itinerant instruction under the Chamber of Agriculture of Pommerania.

The school of agriculture of Grignon, L. BRETONNIERE (*Vie Agr. et Rurale*, 2 (1913), No. 15, pp. 405-409, figs. 4).—The history of the National School of Agriculture of Grignon and its estate is reviewed, and a description given of its practical instruction.

Agricultural instruction for women, D. ZOLLA (*Vie Agr. et Rurale*, 3 (1914), No. 8, pp. 201-203).—The author discusses briefly facilities for instruction in agriculture and home economics for women in Belgium, England, and France.

Agricultural training in the high schools of Nebraska (*Lincoln, Nebr.: Dept. Pub. Instr., 1913, pp. 15, fig. 1*).—This pamphlet contains a copy of the 1913 law providing state aid for agricultural instruction in Nebraska high schools, followed by rules and regulations, and the outlines of 2-year and 4-year courses of study for state-aided rural consolidated, county, and city high schools and of a suggested line of agricultural work for rural schools that may become associated with such approved high schools.

Industrial schools (*Ann. Rpt. Reforms and Prog. Chosen (Korea), 1911-12, pp. 207, 208, 239, 249-255*).—Under the new educational system in Korea, which went into effect in August, 1911, the higher industrial schools may be classified as agricultural, commercial, and technical. At the end of the fiscal year 1911 the industrial schools numbered 19, including 1 agricultural and dendrological school and 15 agricultural schools. There were also 17 elementary industrial schools, of which 13 gave agricultural training and 2 agricultural and commercial training. In the common schools 2 hours a week are devoted to nature study in the third and fourth years. Instruction in elementary agriculture is not compulsory and the time allotted to it may be fixed by the teacher after obtaining the approval of the governor of the province. In the normal course in a higher common school 3 hours a week are devoted to materials for teaching nature study, and in an agricultural school, which offers a 3-year course, generally 10 hours a week the first year and 18 the second are devoted to agricultural subjects out of a total of 30 hours a week.

School manual training practically applied, W. C. DENNIS (*Farmer, 32 (1914), No. 6, pp. 172, 188, figs. 3*).—An account is given of the construction of a model poultry house by the manual training students of the Litchfield, Minn., high school.

Boys' and girls' agricultural clubs in Michigan (*Mich. Farmer, 142 (1914), No. 5, pp. 105, 106, fig. 1*).—A summary is given of a plan for the organization of boys' and girls' clubs throughout the State of Michigan. This is followed by a description of the work done by the Wexford Boys' and Girls' Agricultural Club, which has been in existence for several years.

Agricultural clubs in the high schools of Utah, A. C. CARRINGTON (*Univ. Cal. Jour. Agr., 1 (1913), No. 5, p. 29*).—Within the last year the agricultural club of the Utah College has organized 14 agricultural clubs in the high schools of the State. Arrangements have been made whereby college extension workers and prominent men in the State deliver one lecture a month on an agricultural subject at each club. The work of the clubs this year includes stock and grain judging contests, and some of the clubs have held debates with one another. One club received sample seeds from seed houses in the State, constructed hot-beds and frames, and carried on experiments with seeds and plants in the classrooms. The matured plants were sold, the receipts totaling \$40. Club libraries are also being encouraged.

Wheat competitions in Western Australian schools (*Queensland Agr. Jour., n. ser., 1 (1914), No. 1, pp. 16-20, figs. 2*).—A competition in wheat growing is described in which 3 prizes were awarded for the production of the most grains from an original single grain. The education department supplies tools, fencing, and seeds of flowers, vegetables, and economic plants for gardening lessons in the state schools. Many of these materials are provided by the agricultural department while trees and shrubs are obtained through the forestry department.

Elementary agriculture, G. S. RAYMOND (*Hawaii Ed. Rev., 2 (1914), No. 1, pp. 12, 13, 16*).—This is a suggested outline, prepared by the territorial inspector of schools, of a course in elementary agriculture for the fifth to the eighth grades, inclusive.

Some principles of agriculture (*Hartford, Conn.: Bd. Ed., 1913, pp. 29, figs. 15*).—This is a collection of 23 experiments, gathered from various sources, in plant production, the porosity of an egg, and the length of time required for a hen to molt, followed by an article on Judging Dairy Cows by E. B. Fitts.

Farm animals and farm crops, W. L. NIDA (*Chicago, 1914, pp. VI+238+VII-CLXIX, pl. 1, figs. 114*).—This is the same text as the author's *Elementary Agriculture* previously noted (*E. S. R., 30, p. 598*), with the exception of the addition of a chapter on boys' and girls' clubs and the substitution of 1,000 questions in agriculture and the answers for questions relating to each chapter of the text.

Bulbs: Their selection and best method for planting, MARY T. RONAN (*Rural Educator, 3 (1914), No. 2, p. 27*).—The author describes the planting of 250 hyacinth bulbs in boxes by each class of her school.

The story of wool, SARA W. BASSETT (*Philadelphia, 1913, pp. 213, pl. 1, figs. 5*).—An account is given of the procedure on a sheep farm told in the form of juvenile fiction.

Farm machinery laboratory manual, D. SCOATES (*Agricultural College, Miss., 1913, pp. 48*).—Laboratory exercises in studying farm machinery in use at the Mississippi College are outlined.

Libby's road primer, H. W. LIBBY (*Eugene, Oreg., 1913, pp. 16, figs. 4*).—This primer gives directions for preparing a map and report on a piece of road to be improved, treating earth and sand roads, draining, surfacing, and leveling roads.

A suggestive outline for the study of agricultural or rural economics and rural sociology, C. P. CARY (*Madison, Wis.: State Supt. Pub. Schools, 1913, pp. 31*).—This outline was prepared especially for use in training teachers for country school work, rural economics being one of the subjects in which teachers must be examined in Wisconsin. Methods of teaching the following subjects are suggested: Agriculture as an occupation, the importance of agriculture, history of agriculture, development of the factory system, farming as a business, factors essential to producing the necessities of life, people's needs and wants, transportation, value, marketing of products and prices, agricultural problems, organization of the farm business, farm insurance, the farmer and the State, and country life.

Farm accounts, C. W. SMITH and S. M. THOMAS (*Philadelphia, Chicago, and Des Moines, 1913, pp. 82*).—The purpose of this book is to present simple methods of keeping accounts which the pupils of rural schools will be able to learn and also acquire the habit of using. Each exercise is followed by review questions. It is suggested that instead of being an extra study farm accounts may be substituted for some of the less important topics usually found in the ordinary text-books on arithmetic.

Agricultural supplement to Milne's progressive arithmetic—second book, E. C. BROOKS and I. O. SCHAUB (*New York, Cincinnati, and Chicago, [1914], pp. 305-320*).—In this agricultural supplement, compiled for the schools of North Carolina, the authors call special attention to the business side and value of good farming, the advantage of spraying orchards, the cost of keeping domestic animals, the use of fertilizer, land measurements, the cost and value of good schools and roads, and general farm statistics.

School district agricultural data, S. A. MINEAR (*Rural Educator, 3 (1914), No. 2, pp. 28, 29*).—Directions are given for preparing and using a chart representing an outline map of the school district, on which are shown outlines of the farms of the pupils' parents and data collected by the pupils concerning the acreage, yield, and value of the various farm crops, and the number and value of the live stock.

NOTES.

Arizona University and Station.—The 1914 farmers' short course attracted an attendance of 103. This was an increase of 33 over the previous year and was also deemed encouraging in that a much smaller proportion of students came from the immediate vicinity. A state farm improvement association was organized from among those present to cooperate with the station in studies of farm practice, the dissemination of improved seeds, the organization of local associations, boys' corn clubs, and similar bodies, and otherwise aid in improving farms and farm life.

The extension department has arranged a series of popular agricultural lectures in Phoenix under the auspices of the Y. M. C. A. and the Board of Trade.

It is expected that ground will be broken this spring for the new \$650,000 agricultural building and that this will be completed in 1915.

Arkansas University and Station.—The department of home economics has been transferred from the college of arts and sciences to the college of agriculture and plans laid to enlarge the service of this department.

Arrangements have also been made for the establishment of a plant for the manufacture of antihog cholera serum in connection with a packing plant in Little Rock.

Connecticut College.—A new laboratory course in greenhouse management is to be offered as a senior elective.

The college extension service has been devoting considerable attention to the organizing of the various counties. Murray D. Lincoln, a graduate of the Massachusetts College, has been appointed county agent for New London County beginning April 13. It is expected that an organization will be effected in Hartford County in the near future, while three other counties have the matter under consideration.

L. H. Schwartz has been appointed instructor in poultry beginning about July 1.

Georgia Station.—C. K. McClelland, agronomist of the Hawaii Federal Station, has been appointed agronomist beginning about June 22.

Purdue University.—The establishment of a course in farm management has been authorized by the board of trustees.

Iowa College and Station.—Arthur W. Griffin, formerly of the supervising architect's office of the U. S. Treasury Department, has been appointed assistant chief in agricultural engineering and will make a study of farm structures. Philip L. Blumenthal (Ph. D. Yale) has been appointed assistant chemist.

W. J. Kennedy has resigned as head of the extension work. Paul C. Taff of the extension division has been appointed acting director.

Kansas College and Station.—A 4-year course in highway engineering, optional in the civil and highway engineering course, and a 4-year course in agricultural engineering with three 4-year options in farm machinery, irrigation and drainage engineering, and flour milling, are to be offered.

The enrollment at the beginning of the spring semester was 3,014.

Louisiana Stations.—It has been decided to transfer the irrigation experiment with rice, which has been under way during the past four years, to the Bureau

of Plant Industry of this Department. There will now be provided for this work 30 or more plats properly leveed and equipped with irrigation and drainage canals. A drainage pump will be installed to be used for the double purpose of irrigating these plats and of providing drainage for the station farm. The land previously used for irrigation experiments will be devoted to a 4-year rotation of cotton, corn, soy beans, and cowpeas, and to the growing of miscellaneous crops.

An organization of farmers, known as the Southwest Louisiana Agricultural Society, was formed at a meeting called by the assistant director of the rice substation, March 7, and now has a membership of 43. This society is to meet at the substation monthly during the coming year. Some of the recent meetings have been devoted to a discussion of commercial fertilizers, a study of the data gathered by the station during the past four years, and a discussion of ways and means of charbon eradication.

Massachusetts College.—The 1914 summer schools will include the summer school of agriculture and country life, June 30 to July 28, the school for rural social service July 15 to 28, three boys' agricultural camps of about 10 days each in July, a poultry convention July 22 to 24, and the conference on rural community planning July 28 to August 1. The boys' camps will be conducted under military discipline, with instruction in agriculture, hygiene, citizenship, etc., each forenoon, and with the afternoons and evenings devoted to organized play and recreation, evening campfires, and the like. Each camp will be limited to 30 boys between the ages of 12 and 17, a charge of \$8 a week being made to defray the cost of maintaining the camp, board, instruction, and supervision.

The William R. Sessions fund of \$5,000 has been established by the college following a bequest from the former trustee of the institution.

Bert C. Georgia, instructor in market gardening, died May 24. He was a 1913 graduate of Cornell University and was 25 years of age.

Minnesota University.—W. H. Bender has accepted an appointment as associate professor of agricultural education to take effect the latter part of the summer.

Lincoln Institute, Missouri.—This institution, which is the state agricultural college of Missouri for negroes, has recently purchased a farm of 60 acres about a quarter of a mile from the main campus, for use in teaching agriculture and kindred subjects. Three men are to devote their time to the teaching of agriculture.

New Hampshire College.—Statistics recently collected indicate that of the 4-year students in agriculture during the last 19 years, 70 per cent have come from the farm. Of the graduates during this period, 51 per cent are now engaged in practical farming and 71 per cent of these are farming in New Hampshire. Twenty-five per cent are teachers of agriculture or allied subjects in secondary schools and 23 per cent are in the service of agricultural colleges and experiment stations or of the U. S. Department of Agriculture.

Of the graduates from the 2-year course in agriculture, 77 per cent are now engaged in practical farming. Of those who entered from New Hampshire, 84 per cent remain within the State.

Cornell University.—The fourth session of the School for Leadership in Country Life is announced for June 23 to July 3.

Dr. B. T. Galloway, Assistant Secretary of this Department, has accepted the position of director of the college of agriculture to take effect early in August. O. A. Johannsen and M. F. Barrus have been promoted to full professorships in the departments of entomology and extension work in plant pathology respectively.

North Dakota College.—A "little country theatre," seating about 200 persons, has been fitted up on the second floor of the administration building. It is proposed to utilize this in college work and also as an extension enterprise by disseminating information regarding plays or entertainments deemed adaptable for rural communities.

Ohio State University and Station.—Two types of scholarships have been established in the college of agriculture. In the first, three scholarships of three years each in the short course are assigned to each county, being awarded to the winners in the corn growing and other contests conducted by the state agricultural commission. In addition, the State is divided into four districts, each of which will receive five scholarships of four years each on the basis of a competitive examination on high school agriculture.

Announcement has been made by the agricultural commission that the extension activities of the State will continue to be conducted by the college of agriculture.

A bronze tablet in memory of the late Dr. H. A. Weber, professor of agricultural chemistry for many years, is to be placed in Townshend Hall.

A county experiment farm for Washington County is to be located by the agricultural commission at Fleming, where a tract of 170 acres, mostly hill land, has been selected. A tract of 10 acres, mainly terrace land, about 4 miles north of Marietta will also be used for work with truck crops.

M. C. Thomas and C. Ellis Bundy have been appointed county agricultural agents for Miami and Paulding counties respectively, L. E. Morgan assistant in nutrition, and Miss Mabel Corbould assistant chemist in milling and baking technology in the station.

Porto Rico University.—It is announced that the board of trustees has decided to reorganize the college course on a more elementary or preparatory basis, as most of the students who have entered the college have come direct from the eighth grade and have not been fitted to take up the collegiate work in the various branches of engineering and sciences leading to a degree. The trustees think it will be 10 years or more before there will be a student body available requiring the technical training usually offered by a college of agriculture and mechanic arts.

Virginia Station.—Director S. W. Fletcher has resigned to take effect July 1.

Virginia Truck Station.—Loren B. Smith, a recent graduate of Cornell University, has been appointed assistant state entomologist with headquarters at the Truck Station for the study of truck crop insects.

West Virginia University and Station.—Since the beginning of the year, 13 county agricultural agents, 9 district school superintendents in charge of boys' club organizations, and 9 women county agents in charge of girls' canning clubs have been appointed in cooperation with the farm demonstration work of this Department. During the past winter 24 one-day agricultural schools have been held in as many counties with 867 registrations and 642 visitors, and 11 four-day schools in home economics with 379 registrations and 278 visitors.

J. B. Huyett, president of the State Live Stock Association, has been appointed assistant in animal husbandry in cooperation with this Department and will make a live-stock survey of the State and carry on cooperative experiments in the feeding of beef cattle. F. S. Jacoby, associate professor of poultry husbandry in the Ohio State University, has been appointed temporary assistant for field work in poultry husbandry to study poultry methods, particularly marketing, in Jackson and neighboring counties during June, July, and August. Horace Atwood, the station poultryman, has been appointed agricultural agent for the Panhandle Agricultural Club in Ohio County, but will retain his connec-

tion with the station in supervision of some of the experimental work. Other appointments include R. R. Snapp (University of Illinois 1913) as assistant instructor in animal husbandry and assistant in animal husbandry in the station, effective July 1; H. L. Crane (West Virginia University 1914) as instructor in horticulture and assistant horticulturist, effective July 1; and Henry Dorsey (West Virginia University 1914) as instructor in agronomy and assistant agronomist.

Secondary Instruction in Agriculture.—An agricultural section of the Central Association of Science and Mathematics Teachers is to be established for high school teachers and others interested in secondary instruction in agriculture. A committee consisting of A. W. Nolan, K. L. Hatch, George D. Works, W. H. French, and I. A. Madden, has been appointed to prepare the program and take charge of the selection of officers for the first meeting of the section, to be held in Chicago on November 27 and 28. Among the questions to be discussed at this meeting are (1) the course of study in secondary agriculture, (2) extension work in secondary agriculture, (3) use of land in connection with school agriculture, (4) relation of the high school biological and physical sciences to agriculture, and (5) should emphasis be placed upon a two-year high school vocational course in agriculture, or upon a longer and more general course, or upon a course leading to college work?

Russian Agricultural Budget.—The 1914 budget contains an estimated expenditure for agricultural purposes of £16,638,600, an increase of £2,335,500 over 1913. The largest item is that of £5,300,000 for land organization and agricultural industries, which includes the maintenance of experimental and demonstration agencies, general measures for the development and improvement of various agricultural industries, including forestry, and assistance to peasants in districts under land organization. An allotment of £1,178,700 is estimated for drainage, irrigation, and peat cutting. The allotments for agricultural education and horse breeding are largely increased.

Promotion of Agriculture in Palestine.—The General Council for the Province of Palestine at its recent session appropriated \$1,826 to establish a breeding farm for horses and donkeys; \$13,200 for the establishment of an agricultural school and the transfer of the model farms from Artoof to Sajed and from Jaffa to Hebron; and \$2,640 for the purchase of agricultural implements.

New Journals.—A new publication, *The Annals of the Missouri Botanical Garden*, made its appearance in March. The publication is to be issued quarterly and will contain scientific contributions of members of the staff of the garden, from the Shaw School of Botany, and from visiting botanists working in the garden. It will take the place of the scientific papers formerly published in the annual report of the Missouri Botanical Garden, and the more popular portion of the report will be published in the Missouri Monthly Botanical Garden Bulletin. The annual report will be discontinued.

The American Journal of Botany has recently made its appearance. This new journal is edited by a joint committee of the Botanical Society of America, and is published by cooperative arrangement between the Botanical Society of America and the Brooklyn Botanical Garden.

Insecutor Inscitiæ Menstruus is a monthly journal of entomology conducted by Harrison G. Dyar, Ph. D., and established in memory of Augustus Radcliffe Grote. It will deal especially with descriptions of species and genera, life histories, and similar material. The initial number is made up of notes on cotton moths by Dr. Dyar.

The division of agricultural education of the department of agriculture in the University of Minnesota has begun the monthly publication of *The Visitor*,

devoted to the interests of agriculture, manual training, and home economics in Minnesota high schools.

Allgäuer Monatschrift für Milchwirtschaft und Viehzucht is being published as the official organ of the dairy union of Allgau in Wurttemberg, with Dr. Kurt Teichert as editor. The initial number contains popular articles, reports of meetings, notes, reviews, etc.

Wiener Tierärztliche Monatschrift is being issued monthly in the interests of both practical and scientific veterinary medicine. It will contain original articles, abstracts, notes, etc.

The Illinois State Horticultural Society is publishing *Illinois Horticulture* as its official organ. Members of the staff of the Illinois University and Station are among the contributors.

Boletín de Bosques, Pesca, i Caza is the first publication of the kind to be issued in Chile. The subjects considered are treated chiefly in their industrial, commercial, and economic aspects.

The Banker and Farmer is being published monthly by the Agricultural Commission of the American Bankers' Association. The initial number deals especially with agricultural credit and farm demonstration work.

Buletino ufficiale della Associazione Orticola Professionale Italiana is a monthly of which Dr. Gustavo Vagliasendi is editor. It is devoted largely to official announcements and brief notes.

The National Field is being published as a weekly at Atlanta, Ga., as the official organ of the National Farmers' Union.

The Agricultural Journal, printed in Chinese, is being issued by the Chinese Department of Agriculture and Forestry.

Agricultural Schools in Panama.—Two agricultural schools are to be established in Panama. J. René Piot, agronomical engineer of Paris, has been selected as director of one of the schools, which will be located near New Gorgona. The government is also contemplating the establishment of an agricultural experiment station.

Miscellaneous.—*The London Times* announces that the trustees of the estate of the late H. B. Noble of Douglas, Isle of Man, have decided to devote \$100,000 to the fostering of agriculture on that island. It is expected that a board of agriculture will be established to administer the fund and additional moneys to be obtained from the island.

The London School of Tropical Medicine has sent an expedition to China to study the mode of dissemination of human diseases caused by trematode parasites, and the relation of such diseases to those occurring in domestic animals.

An additional department of animal pathology has been established in the Rockefeller Institute. Prof. Theobald Smith of Harvard University has been placed in charge of the new work.

F. W. Taylor, director of agriculture in the Philippine Islands, has resigned and will return to this country, and has been succeeded by H. T. Edwards, the former vice-director.

Dr. Otto May, honorary professor of agriculture at the Technical School of Munich, has died at the age of 81 years.

CONTENTS OF VOL. XXX, NO. 9.

	Page.
Recent work in agricultural science.....	801
Notes.....	900

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Introduction to biochemistry, Löb.....	801
Bearing of osmotic pressure on physical or general chemistry, Jones.....	801
Reduction of arsenic acid to arsenious acid by thiosulphuric acid, Chapin.....	801
The formation of hydrocyanic acid from proteins, Emerson, Cady, and Bailey.....	802
The production of hydrocyanic acid by bacteria, Clawson and Young.....	802
About the formation of betain in animals and plants, Ackermann.....	803
Crystallized polysaccharids from starch, Pringsheim and Langhans.....	803
Crystallization of cream of tartar in the fruit of grapes, Alwood.....	803
The seeds and seed oil of bilberries and cranberries, Diedrichs.....	803
The hemagglutinating and precipitating properties of the bean, Schneider.....	804
The chemical composition of some fungi, Winterstein, Reuter, and Korolew.....	804
The behavior of fungi toward phytin, Jegoroff.....	805
Citric acid formation from glycerin by fungi, Wehmer.....	805
Amygdalase and amygdalinase in <i>Aspergillus</i> , Javillier and Tchernoroutsky.....	805
Studies on enzym action.—VI, The specificity of lipase action, Falk.....	806
Studies on enzym action.—VII, Action of amino acids on esters, Hamlin.....	806
Cleavage of saccharose by acids with invertase, Bertrand and Rosenblatt.....	806
Some properties of koji-diastrase, Kita.....	806
The determination of nitrogen in organic substances, Herzfeld.....	807
The colloid matter of clay and its measurement, Ashley.....	807

About the determination of colloid substances in the soil, Rohland.....	807
A contribution to the estimation of colloids in soils, I, Górski.....	807
Soil carbonates.—A new method of determination, MacIntire and Willis.....	808
Examination of artificial fertilizers.....	809
Application of the microscope to the analysis of fertilizers, Collin.....	809
Determination of water-soluble phosphoric acid in superphosphates, Pilz.....	809
Soluble silicic acid in Thomas slag powder and its influence, Popp et al.....	809
Determination of citric acid-soluble phosphoric acid in slag, Simmermacher....	809
The detection of alum in bread, Van Kregten.....	809
Estimation of xanthin basis in cocoa, tea, coffee, Camilla and Pertusi.....	810
The Babcock test with special reference to testing cream, Ross and McInerney..	810
The kinetics of the inversion of sucrose by invertase, Hudson.....	811
Inversion of cane sugar with ammonium chlorid, Strohmmer and Fallada.....	811
Corrected inversion method according to Clerget, Saillard.....	811
Decomposition of glutamates on heating in aqueous solution, Staněk.....	811
A revision of the hundred point of the saccharimeter, Bates and Jackson.....	812
The determination of raffinose in the sugar beet, Nowakowski and Muszynski....	812
Examination of commercial starch.....	813
Examination and judgment of vegetable tanning substances.....	813
Determination of fat in feeds, with reference to trichlorethylene, Neumann....	813
Homemade cider vinegar, Sackett.....	813
Pineapple vinegar, Kelley.....	813
Utilization of waste oranges, Cruess.....	814

METEOROLOGY—WATER.

The weather element in American climates, Ward.....	814
The frostless period in Maryland and Delaware, Fassig.....	814
Soil moisture and agricultural meteorology, Gèze.....	814
Is the earth drying up? Gregory.....	815
Is South Africa drying up? von Gernet.....	815
Secular variation of precipitation in the United States, Henry.....	815
The snowfall about the Great Lakes, Brooks.....	815
Nitrogen and chlorin in rain and snow, Wiesner.....	815
The sterilization of water by ultraviolet rays, Silbermann.....	816
Metropolitan sewage farm, Laughton.....	816

SOILS—FERTILIZERS.

Estimation of the surface of soils, Hanley.....	816
Study of physical analysis of fine particles of clay, Müntz and Gaudechon....	817
Soil investigations, Ames and Gaither.....	817
The red clay soil of Porto Rico, Gile and Ageton.....	818
Soils, Auchinleck.....	818
Studies of meteoric waters, soil, and air, Müntz and Lainé.....	818
The nitrifying efficiency of certain Colorado soils, Sackett.....	818
Examination of some more and less productive sections of a field, Lyon et al....	819
The rational improvement of Cumberland Plateau soils, Mooers.....	820
The rational improvement of Highland Rim soils, Mooers.....	821
The applications of electricity to agriculture, Baker.....	821
The relation of fertilizers to soil fertility, Guthrie.....	821
The use of commercial fertilizers, Barker.....	821
Mixed applications of calcium cyanamid and sodium nitrate, Bolin.....	822
Using crude phosphates and limes containing silica as manures, Pfeiffer.....	822
Ground limestone for soil improvement, Barker.....	822
Pennsylvania limestone and lime supplies, Frear.....	822
Molasses and chlorinated lime as a soil ameliorant, Harrison and Ward.....	822
Trials with molasses as a sugar-cane manure, Ebbels.....	822
The fertilizing action of sulphur on grapes, Vermorel.....	822
The action of manganese in soils, Skinner, Sullivan, et al.....	823
Commercial fertilizers: Inspection 1913, Hite and Kunst.....	823

AGRICULTURAL BOTANY.

The chemical dynamics of living protoplasm, Osterhout.....	823
Behavior of inorganic nitrogenous plant food materials in sunlight, Baudisch..	823
Effect of manganese and aluminum on plant development, Pfeiffer and Blanck....	824

	Page.
Influence of metals on <i>Aspergillus niger</i> in Raulin's liquid, Bornand.....	824
A contribution to the theory of antagonism, Osterhout.....	824
Effect of antagonistic or balanced solutions on growth of corn, Caldwell.....	824
The harmful action of distilled water, True.....	825
Radio-activity and vegetation, Vacher.....	825
The physiology of the rest period in potato tubers, Appleman.....	825
Biochemical study of after-ripening in the potato tuber, Appleman.....	825
Metabolic changes in potato tubers during sprouting, Appleman.....	825
Differential permeability, Osterhout.....	826
Inefficacy of cultivation for destroying weed seeds, Munerati.....	826
Recent contributions on problems regarding mycorrhiza, Peklo.....	826
The counting of protozoa in soil, Killer.....	826
A study of certain floral abnormalities in Nicotiana, White.....	826
Notes on root variation in some desert plants, Cannon.....	827

FIELD CROPS.

Growing crops and plants by electricity, Dudgeon.....	827
Experiments on the influence of electricity upon plant growth, Schikorra.....	827
Experiments in the application of electricity to crop production, Priestley.....	828
Report of the agronomist, McClelland.....	828
[Field crops work at the Glenwood substation], Clowes.....	828
Experiments with leguminous plants, Sahr.....	828
Botanical considerations affecting the care of grass land, Stapledon.....	828
Pastures and pasture grasses for Utah, Harris.....	829
Variety tests of field crops in Utah, Harris and Hogenson.....	829
Division of cereals: Summary of results, 1913, Saunders et al.....	829
Preparing land for grain crops on the prairies, Grisdale.....	829
Experiments concerning top-dressing of timothy and alfalfa, Lyon and Bizzell.....	829
[Wheat and rye in Turkestan], Benzin.....	830
A study of statistical methods with barley, Whitcomb.....	830
Experiments with beans (<i>Poroto mantecoso</i>), Alvarez.....	830
Ear characters not correlated with yield in corn, McCall and Wheeler.....	830
Corn growing in Manitoba, McKillican.....	830
Annual report of the Nebraska Corn Improvers' Association.....	831
Variety tests of cotton for 1913, and the past eleven years, Winters.....	831
The Knapp method of growing cotton, Mercier and Savely.....	831
Standard tests for hemp, Anderson.....	831
Sisal hemp: Planting, manufacturing, and general management, Stoddart.....	831
Cultivation of main-crop potatoes.....	832
Potato production from experience, Twitchell.....	832
Some experiments on the growth of rice in water culture, Villegas.....	832
Influence of salts common in alkali soils on the growth of rice, Miyake.....	833
On the composition of rice of Siam, Liberi.....	834
Influence of variety, preceding crop, fertilizer, and stand on rye, Gerlach.....	834
Soy beans in South Africa, Thompson.....	834
A seven-year variety test with stock beets, 1904-1910, Böhmer.....	834
Annual comparison of the quality of sugar-beet seeds, Urban.....	834
On the influence of flowers of sulphur on the growth of sugar beets, Urban.....	834
Seedling canes and manurial experiments, d'Albuquerque et al.....	835
Studies on the tobacco crop of Connecticut, Jenkins.....	835
Studies upon influences affecting the protein content of wheat, Shaw.....	836
The germination of wheat treated with fungicides and insecticides, Picchio.....	837
Methods of seed germination tests, Pieper.....	837
Influence of moisture, temperature, and oxygen on stored seeds, Heinrich.....	837
Weed exterminator.....	837
<i>Polygonum (Fagopyrum) tataricum</i> as a weed in buckwheat fields, Kamensky.....	838
Apparatus for taking soil samples, Schewelew.....	838

HORTICULTURE.

Report of the horticulturist, Higgins.....	838
Fertilizer experiments with tomatoes, Dacy.....	839
Hardiness of fruit buds and flowers to frost, Garcia and Rigney.....	839
Experiments in the dusting and spraying of apples, Blodgett.....	840
Plum culture and lists of plums suitable for Canada with descriptions, Macoun.....	840

Grafting <i>Vinifera</i> vineyards, Bioletti.....	Page 841
[Banana investigations at the Hilo substation], Clowes.....	841
Factors governing successful shipment of Florida oranges, Stubenrauch et al....	841
The papaya in Hawaii, Higgins and Holt.....	841
Top-working seedling pecan trees, Hutt.....	843

FORESTRY.

Trees and how they grow, Nuttall.....	843
Balsam fir, Zon.....	843
Tests of Rocky Mountain woods for telephone poles, Betts and Heim.....	843
Tyloses: Their occurrence and significance in some American woods, Gerry....	844
Tyloses: Their occurrence and significance in some American woods, Gerry....	844
The selection system in forest economy, Kubelka.....	844
The present conditions of forestry in Italy, Piccioli.....	844
Progress report of forest administration in Baluchistan for 1912-13, Mulraj.....	844
The lumber industry.—I, Standing timber.....	844
The lumber industry.....	845
Forest products.....	845

DISEASES OF PLANTS.

Proceedings under the destructive insects and pests acts, Rogers.....	845
Annual report on mycology, Butler.....	845
Report on mycology, Butler.....	845
The control of damping-off disease in plant beds, Johnson.....	846
The relation of <i>Fusarium nivale</i> to <i>Nectria graminicola</i> , Weese.....	846
Some imperfect fungi isolated from wheat, oat, and barley plants, Johnson....	846
The culture of cereal rusts in the greenhouse, Fromme.....	846
Report of 1908-1912 studies on celery diseases in Hamburg lowlands, Klebahn....	847
Diseases of the potato tuber and the selection of sound seed, Jack.....	847
The perennial mycelium of <i>Phytophthora infestans</i> , Melhus.....	847
Spraying of potato crop, McDonald and McKenzie.....	847
A disease of spinach, Passy.....	847
A leaf curl of tobacco in Kamerun, Ludwigs.....	848
Finger-and-toe experiments, Manson.....	848
Finger-and-toe, Pardy.....	848
Manuring and variety tests with turnips for finger-and-toe disease, Fowlie....	848
Scab disease of apples, Wallace.....	848
The yellow leaf disease of cherry and plum in nursery stock, Stewart.....	848
Diseases of young grapevines, Ravaz.....	849
Recent observations on <i>Stilbum flavidum</i>	849
[Notes on tea diseases], Tunstall.....	849
Leaf roll and starch storing in <i>Syringa</i> , Laubert.....	849
Immunity in plants, Ordnung.....	849
Methods of propagation of mistletoe and the injury caused by that parasite....	849
Nodules on <i>Hevea</i> rubber trees, Anstead.....	850
Disease of Para rubber trees, Rutter.....	850
Dry rot investigations, Möller.....	850
Dry rot in factory timbers, Hoxie.....	850

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Catalogue of the mammals of western Europe in the British Museum, Miller.....	850
The fauna of the German colonies, Aulmann.....	851
Relative efficiency of rat traps in Manila, Heiser.....	851
The birds of North and Middle America, Ridgway.....	851
The bobolink (<i>Dolichonyx oryzivorus</i>) as a conveyor of Mollusca, Ramsden.....	851
An unusual observation on the crow at Lubec, Maine, Clark.....	851
A new bacillus isolated during an epidemic among frogs, Venulet and Padlewski....	851
Handbook of entomology, edited by Schröder.....	851
Treatise on forest entomology, Barbey.....	851
A text-book of medical entomology, Patton and Cragg.....	852
A contribution to exact biology, Handlirsch.....	852
Entomological research committee report for 1912-13.....	852
[Entomological investigations in Ontario], Caesar and Baker.....	852

	Page.
Report of the entomologist, Fullaway.....	852
Insects and other galls of plants in Europe and Mediterranean Basin, Houard ..	852
Carnivorous insects in the region of Paris, Chrétien.....	853
Report of the government entomologist to March 31, 1913, Fletcher.....	853
Insect enemies of plants in Surinam, Kuiper.....	853
Animal enemies and diseases of the sugar beet in 1912, Stift.....	853
Insect pests of truck and garden crops, 1913, Lovett.....	853
Apple insects, Schoene and Fulton.....	853
Injurious citrus insects, Cook.....	853
Termites or white ants.....	853
A reduviid in which <i>Trypanosoma cruzi</i> develops, Brumpt and Gonzalez-Lugo.....	853
Reduviidæ of North America capable of transmitting <i>T. cruzi</i> , Brumpt.....	853
The tea seed bug, Antram.....	853
The wheat bug (<i>Elia germari cognata</i>).....	854
Contribution to the study of Helopeltis, Bernard.....	854
The avocado membracid (<i>Hoplophora monogramma</i>), Inda.....	854
On the Chermesidæ of Switzerland, Cholodkovsky.....	854
The mealy bugs of California, Essig.....	854
Woolly aphids of the elm, Patch.....	854
Silkworm experiments, Woodworth.....	854
The brown-tail moth (<i>Euproctis chrysorrhæa</i>), Britton.....	854
The sugar-cane borer (<i>Diatraea saccharalis oblitteralis</i>), Rosenfeld and Barber.....	854
<i>Hypsopygia constalis</i> , injurious to lucern hay in the Romagna, Italy, Sbrozzi.....	854
The Chelonia caterpillars, Picard.....	855
<i>Tapinostola musculosa</i> , a noctuid injurious to cereals in Hungary, Jablonowsky.....	855
The flight of the house fly, Hindle.....	855
The cambium miner in river birch, Greene.....	855
Some common lady beetles of Connecticut, Britton.....	856
<i>Scydmaenus chevalieri</i> n. sp. in Senegal, Vuillet.....	856
A new endemic fern weevil of the genus <i>Heteramphus</i> , Swezey.....	856
The weevils of the families Attelabidæ and Brachyrhinidæ, Pierce.....	856
Biology of the large brown pine beetle and remedial measures, Grohmann.....	856
A contribution to the comparative physiology of digestion, Petersen.....	856
Apiculture in British Columbia, Harris and Todd.....	856
A new braconid parasite of <i>Sinoxylon sexdentatum</i> in grapevine shoots, Picard.....	856
On a new species of Mymaridæ from Trinidad, Waterhouse.....	856
A new species of Corymbites from the Sonoran zone of Washington, Hyslop.....	856
Studies on the habits and development of <i>Spalangia muscidarum</i> , Richardson.....	856
Notes on Tetrastichini, Kurdjumov.....	857
Protozoan parasites of Ichneumonidæ, Morley.....	857
The cherry fruit sawfly (<i>Hoplocampa cookei</i>), Essig.....	857
The occurrence of a tenthredinid (<i>Emphytus braccatus</i>) on the oak, Nielsen.....	857
Ticks in the West Indies.....	857
The Brazilian species of the subfamily Heterakinæ, Travassos.....	857

FOODS—HUMAN NUTRITION.

Some results of a study of the factors of bread making, Williams.....	857
The staling of bread, Verschaffelt.....	859
"Lime bread".....	859
"Biological properties" of milk in relation to feeding infants, Lane-Claypon.....	859
Present knowledge regarding the putrefaction of butcher's meat, Grimaldi.....	861
The nitrogen content of mince meat, Utt.....	861
Meat extracts, McGill.....	861
Notes on the history of preserving fish, Beel.....	861
Conserving the nitrogenous material in dried codfish, Yoshimura and Kanai.....	861
Reprocessed canned salmon—possible danger from its use as a food.....	861
Dried and packaged fruit, McGill.....	861
Preserves, Collin.....	862
The digestibility of the nitrogenous material in cocoa and cocoa shells, Goy.....	862
Celery seed, Juillet.....	862
Proceedings of Association of American Dairy, Food, and Drug Officials, 1913.....	862
Report of Commonwealth and States of Australia on food and drugs standards.....	862
The new cookery, Cooper.....	862
Cooking by G. A. S., compiled by Edden, edited by Brereton.....	862
[Electricity for cooking and heating].....	862

	Page.
Value of sanitation as applied to railway and other corporations, Thrush.....	862
Healthy employees in kitchen and dining room, Homan.....	863
Clean hands [in relation to food sanitation].....	863
Notes on the increased cost of living, Duckworth.....	863
Domestic economy—the family budget, Fletcher.....	863
Studies from the department of physiology, II.....	863
The absolute vegetarian diet of Japanese monks, III, IV, Yukawa.....	863
Rate of elimination of nitrogen as influenced by diet, Mendel and Lewis.....	864
Variations in excretion of endogenous uric acid from diet, Graham and Poulton.....	864
Alleged excretion of creatin in carbohydrate starvation, Graham and Poulton.....	864
On fat absorption.—III, Changes in fat during absorption, Bloor.....	864
Further experiments concerning digestion in dogs, London et al.....	865
Growth with food containing vitamin and with vitamin-free food, Funk.....	865
Studies on pellagra.—I, Influence of the milling of maize on the meal, Funk.....	865
The physiological value of the vitamins, Funk.....	866
Studies on water drinking: XIII, Fasting studies, VIII, Howe and Hawk.....	866
Fasting studies.—IX, Leucocyte count during fasting, Howe and Hawk.....	866
Fasting studies.—X, A note on a glycogen-free liver, Hawk.....	867
Relation of fatigue to CO ₂ output during static muscular work, Frumerie.....	867

ANIMAL PRODUCTION.

Calcium and phosphorus of farm feeds, and animal's requirements, Hart et al.....	867
Studies of the natural pasture grasses of Uruguay, Puig y Nattino.....	868
Sugar-beet pulp for feeding live stock.....	868
Commercial feeding stuffs, Street.....	868
Commercial feeding stuffs of Pennsylvania in 1912, Kellogg et al.....	868
Animal economy section.....	868
Division of animal husbandry.....	868
Studies on the prehistoric Moravian cattle, Mohapl.....	869
The Flemish breed of cattle, Raquet.....	869
Studies on Hannaberner cattle, Mohapl.....	869
Studies on the Irish Kerry cattle, Lundwall.....	869
White cattle of Italy, Stewart.....	869
Inbreeding and heredity studies with cattle of West Prussian herd book, Hesse.....	869
Experiments in steer feeding in Manitoba, McKillican.....	869
Cattle-feeding experiments, Bruce.....	870
The sheep of Bosnia and Herzegovina, Mehmedbasic.....	870
Fecundity of sheep, Ainsworth-Davis and Turner.....	870
Annual wool review for 1913, Battison.....	870
The swine of the Laibach moor and relation to an extinct race, Ulmansky.....	871
Brood sows and their litters, Hill.....	871
Body, heart, and lung weights of improved native and Berkshire swine, Semmler.....	871
Effect of nonprotein nitrogen compounds upon the nitrogen intake, Köhler.....	871
The Missouri saddle horse, Trowbridge, Jackson, et al.....	872
Report of the stallion enrollment board of Ontario, 1913.....	872
Proceedings of the American Poultry Association.....	872
Our domestic birds, Robinson.....	872
Farm poultry, Graham and McCulloch.....	872
Poultry keeping on the farm, Cooley et al.....	872
Origin and early history of the primordial germ cells in the chick, Swift.....	872
Electrified chickens.—Electricity as a growth stimulator.....	873
On the ability of chickens to digest small pieces of aluminum, Curtis.....	873
The 300-egg hen, Dryden.....	873
Practical packages for egg marketing.....	873
The Indian Runner duck book, Valentine.....	873
Goose fattening in Germany, Schilling.....	873
Experiments with ostriches.—XXII, The development of the feather, Duerden.....	874
Ostrich breeding.—The preparation and trade of the plume, Menegaux.....	874
A pedigree system for use in breeding guinea pigs and rabbits, Surface.....	874
Guinea pigs, Clarke.....	874

DAIRY FARMING—DAIRYING.

Soiling crops <i>v.</i> silage for dairy cows in summer, Woll et al.....	874
[Studies on the fat, total solids, and dirt content of milk], Fischer.....	875
Constants for normal variation in the fat content of mixed milk, Pearl.....	875

	Page.
Testing milk and cream for butter fat, Hunziker.....	875
Origin of some of the streptococci found in milk, Rogers and Dahlberg.....	875
Dirt sediment testing.—A factor in obtaining clean milk, Schroeder.....	876
Minnesota dairy and food laws.....	877
The dairy industry in New York State.....	877
Distribution of moisture and salt in butter, Guthrie and Ross.....	877
Some factors influencing yield and moisture content of Cheddar cheese, Fisk.....	877
Manufacture of cheeses from skimmed cow's milk and whole goat's milk, Kraemer.....	878

VETERINARY MEDICINE.

An introduction to the study of infection and immunity, Simon.....	878
Experimental production of agglutinins in animals by salvarsan, Nicolas et al.....	878
The toxicity of fungi; their hemolytic power, Parisot and Vernier.....	878
Union between <i>Amanita</i> hemolysin and antihemolysin, Ford and Rockwood.....	879
Note on the <i>Amanita</i> toxin, Ford and Bronson.....	879
Action of extracts from <i>boletus</i> and <i>chanterelle</i> , Friedberger and Brossa.....	879
Serum for protein of <i>Agaricus muscarius</i> , Galli-Valerio and Bornand.....	880
Cicuta, or water hemlock, Marsh, Clawson, and Marsh.....	880
Influence of subcutaneous mallein test on blood examination in glanders, Marcis.....	881
The effect of cold upon the larvæ of <i>Trichinella spiralis</i> , Ransom.....	881
<i>Trypanosoma americanum</i> , Johns.....	882
The relation of human tuberculosis to bovine tuberculosis, Izcarra.....	882
About atypical tuberculosis in slaughtered animals, Hafemann and Binder.....	882
[About atypical tuberculosis in slaughtered animals], Hafemann and Binder.....	882
The intradermal test for tuberculosis in cattle and hogs, Haring and Bell.....	883
Texas or tick fever, Mohler.....	884
Actinomycosis of the mammary gland in dairy herds in Victoria, Kendall.....	884
A bovine disease caused by the <i>Bacillus necrophorus</i> , Balogh.....	884
Care of the teeth in dairy cattle, Cullen.....	884
<i>Strongylus capillaris</i> of the camel, Pricolo.....	884
A study of epithelioma contagiosum of the common fowl, Sweet.....	884

RURAL ENGINEERING.

Frictional resistance in artificial waterways, Cone, Trimble, and Jones.....	885
A comparison of formulas for estimating run-off, Cunningham.....	886
Irrigation experiments at Gross Enzersdorf (Austria).....	886
Irrigation experiments with brackish water, Bordiga.....	886
Federal v. private irrigation, Henny.....	887
State rivers and water supply commission.....	887
Measuring devices [irrigation], Etcheverry.....	887
Pumping and other machinery, Musto.....	887
Designing water conduits of large diameter, Janni.....	887
Farm drainage, Brown.....	887
The road problem, Macdonald.....	888
Mechanical engineering aspects of road construction, Crompton.....	888
Construction of bitumen-bound broken stone roads, Smith.....	888
Agricultural surveying laboratory manual, Scoates.....	888
Variations in results of sieving with standard cement sieves, Wig and Pearson.....	888
French tests on oil-mixed concrete, Feret.....	889
Effect of hydrated lime on Portland cement mortars, Spackman.....	889
Cement pipes and distributing stand pipes, Etcheverry.....	889
Some data on reinforcing concrete pipe, Sims.....	889
Transverse strength of screws in wood, Kolberk and Birnbaum.....	889
Sun-power plant.....	890
Utilizing waste heat of a small gas engine.....	890
An experimental study in multiple effect evaporation, Deerr.....	890
The heat balance of a cane-sugar factory, Deerr.....	891
Central station power for farmers, Palmquist.....	891
Ruralizing electricity, Davidson.....	892
Harvesting ice with central-station energy.....	892
Farm machinery laboratory manual, Scoates.....	892
Agricultural machines and implements, Hagmann.....	892
Solving the fuel problem for the motor truck, Slauson.....	892
Some experiments with steam threshing machinery at Cawnpore, Burt.....	892
Farm building construction, Smith.....	892

	Page.
[Farm building, planning, and construction].....	892
Cheaply constructed tanks, Ward.....	893
The construction of dipping tanks for cattle.....	893
Modern practice in heating and ventilation, X, XII, King.....	893
Sizes of pipe for gravity hot water [heating] systems, Cooley.....	893
Good and bad plumbing installations.....	893

RURAL ECONOMICS.

Rural versus urban: Their conflict and its causes, Bookwalter.....	893
The church and the rural community, Wilson.....	893
The rural housing question, Phillips.....	894
England's foundation: Agriculture and the State, Mills.....	894
How shall farmers organize? Camp.....	894
Report of the agricultural credit commission of Saskatchewan, 1913.....	894
Report of the mutual agricultural credit banks and results in 1912, Raynaud..	894
The garden to table express, Miller.....	894
The drift to the city in relation to the rural problem, Gillette.....	895
The movement of rural population in Illinois, Hoagland.....	895

EXPERIMENT STATION RECORD.

VOL. XXX.

ABSTRACT NUMBER.

No. 9.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Introduction to biochemistry, W. LÖB (*Einführung in die Biochemie*, Leipzig, 1911, pp. 83, figs. 12).—This is a small book intended to serve as an introduction to biochemistry. It is a compilation of a series of lectures given in public high schools. The plant and animal kingdom are both considered.

The bearing of osmotic pressure on the development of physical or general chemistry, H. C. JONES (*Plant World*, 16 (1913), No. 3, pp. 73-88).—This topic is discussed for the purpose of showing its importance in relation to the biologic sciences.

The reduction of arsenic acid to arsenious acid by thiosulphuric acid, R. M. CHAPIN (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 6, pp. 515-517).—"While endeavoring to work out a practicable field method for the estimation of the total arsenic—that is, a method which should include both arsenites and arsenates—in arsenical baths used for dipping cattle, studies were made upon the effect of various reducing agents which are able to absorb iodine in acid solution upon the well-known reversible reaction, $\text{As}(\text{OH})_3 + 2\text{I} + 2\text{H}_2\text{O} \rightleftharpoons \text{As}(\text{OH})_5 + 2\text{HI}$. Unless the solution in which this reaction is taking place is freely acidified with a strong mineral acid or heated, the progress of the reaction from right to left is inconveniently slow."

It was found, however, that sodium thiosulphate greatly aided the reduction, and further, that the presence of hydriodic acid played no part in the reduction of arsenic to arsenious acid. This reaction can be effected by sodium thiosulphate and mineral acid alone.

The present series of experiments was limited to a study of the reactions occurring when a mixture of arsenic acid, or arsenate, with an excess of sodium thiosulphate is acidified with a definite amount of hydrochloric or sulphuric acid, as this condition must prevail in any quantitative method for the determination of arsenic based on these reactions. The solutions employed were "(1) a tenth-normal (oxidimetric) solution of arsenic acid prepared by oxidizing arsenious acid with nitric acid and expelling excess of the latter, (2) a tenth-normal solution of sodium thiosulphate, (3) a twentieth-normal solution of iodine, free from iodate, and (4) normal hydrochloric acid."

From the experiments it is obvious that the action of thiosulphuric acid upon arsenic acid appears to be closely similar to the action of thiosulphuric acid on bichromic acid. A small amount of the thiosulphuric acid is decomposed into sulphur dioxide, and presumably, sulphur, but this does not become evident.

Most of the sulphur reacts with tetrathionic acid to form pentathionic acid and the remainder is in a colloidal solution. "The presence of pentathionic acid was here shown in a similar manner on several of the mixtures, while they still remained clear, by neutralizing with caustic alkali, using methyl orange as indicator. As the neutral point was reached, a distinct opalescence appeared which was not affected by hydrochloric acid, but which was dissolved after a time by excess of caustic alkali."

"For obvious reasons it is not likely that the reaction here noted, apparently for the first time, will afford the basis for a desirable volumetric method for use in the laboratory. It may be of value as a convenient means for reducing arsenic acid to arsenious acid preliminary to precipitation by hydrogen sulphid. As a basis for a field test, in default of anything better, it does offer some promise, and experiments in that direction are now under way."

On the formation of hydrocyanic acid from proteins, H. W. EMERSON, H. P. CADY, and E. H. S. BAILEY (*Jour. Biol. Chem.*, 15 (1913), No. 3, pp. 415-417).—Certain organisms, as for instance *Bacillus pyocyaneus*, will produce hydrocyanic acid when grown on egg. The yolk seems to be a more favorable medium for hydrocyanic acid production than the white.

For the first experiments in this work eggs contaminated with bacteria were broken, the whites separated from the yolk, and distributed into wide-mouthed 500 cc. flasks so that each flask contained either the whites or the yolks of 2 eggs. The flasks were loosely stoppered, put in a warm place, and tested each day by the Schönbein test for hydrocyanic acid. Seventy-four experiments were started in 9 different series, and in 8 experiments from 6 different series, after intervals varying from 4 days to 14 days, the egg substance evolved hydrocyanic acid. In a number of such cases crystals were obtained which looked like silver cyanid although the silver nitrate was darkened by the hydrogen sulphid, but the authors were not able to get positive results with the Prussian blue test. The yolks developed hydrocyanic acid in 6 cases and the whites in 2 cases.

Hydrocyanic acid was developed best when the organism was grown on a protein medium slightly acid to litmus and phenolphthalein. When hydrochloric acid is present to an extent where it may be detected by the usual methods, hydrocyanic acid is not produced.

Preliminary report on the production of hydrocyanic acid by bacteria, B. J. CLAWSON and C. C. YOUNG (*Jour. Biol. Chem.*, 15 (1913), No. 3, pp. 419-422).—A description of the biological features of one of the organisms isolated in the investigation described above. It is shown that the power "which the organism has of producing HCN is apparently not due to an extracellular enzyme. The organism was grown in gelatin for 72 hours at 37° C. and had been giving off HCN for 48 hours. After filtering through a Berkefeld filter, some of the filtrate was planted again into gelatin and incubated, but gave negative results for HCN. Hydrocyanic acid gas is apparently produced only under aerobic conditions, which led to the belief that the reaction in which HCN was produced was due to oxidation of the proteins. This was subsequently shown to be true. . . . Several other strains of *Bacillus pyocyaneus* were tested for HCN production, all of which returned positive results."

B. pyocyaneus was not the only organism capable of producing hydrocyanic acid, as an unnamed organism isolated from the soil and a culture of *B. violaceus* growing upon gelatin and egg produced it also. "There has been much work done on the production of HCN from grain, beans, linseed meal, germinating *Sorghum vulgare*, and other protein-containing substances. In most cases the production of HCN is attributed to an enzyme. Apparently all of the workers were using nonsterile material, which could have been easily contaminated by an HCN-producing organism."

About the formation of betain in animals and plants, ACKERMANN (*Abs. in Berlin. Klin. Wchnschr.*, 50 (1913), No. 26, p. 1235).—This is a study in regard to the method whereby betain is elaborated in the organism. Initial experiments were made with dogs and glyecocoll but the results were negative. Sugar beets kept for six weeks in water cultures containing glyecocoll showed no greater content of betain than beets grown in a medium free from glyecocoll. On the other hand if β -pyridincarboxylic acid, i. e., nicotinic acid, is given to plants or animals, a synthesis seems to take place.

Crystallized polysaccharids from starch, H. PRINGSHEIM and A. LANGHANS (*Ber. Deut. Chem. Gesell.*, 45 (1912), No. 12, pp. 2533–2546; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 601, I, pp. 832, 833).—"The generic term 'amylose' is suggested for the polysaccharids of the formula $(C_6H_{10}O_5)_n$. Dextrin- β , which decomposes at 268° C., is too sparingly soluble in water for accurate cryoscopy, but dextrin- α (tetra-amylose), decomposing at 292° , proves to have a molecular weight $(C_6H_{10}O_5)_4$. Both forms are acetylated by acetic anhydrid in the presence of zinc chlorid, but scission of the molecules occurs at the same time; dextrin- α yields the hexa-acetate of a diamylose, needles, decomposing at 151.5 to 152.5° (correction $[a]_D^{24} + 100.6^\circ$ in acetic acid), while dextrin- β gives the mona-acetate of a triamylose, tablets, decomposing at 142° (correction $[a]_D^{24} + 112.6^\circ$ in acetic acid). Hydrolysis of these acetates by cold alcoholic potassium hydroxid produces respectively diamylose $(C_6H_{10}O_5)_2$ (decomposing at about 300° , $[a]_D^{24} + 136.2^\circ$ in water), which crystallizes from water in needles with $2H_2O$, and triamylose, $(C_6H_{10}O_5)_3$, needles, crystallizing with $4H_2O$, decomposing near 300° ; $[a]_D^{24} + 151.8^\circ$ in water. Crystallographic details of the above amyloses are given."

Crystallization of cream of tartar in the fruit of grapes, W. B. ALWOOD (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 6, pp. 513, 514).—During a chemical examination made of the ripening fruit of grapes the analytical results were so affected as to lead to the belief that a deposition of the acid salt of bitartrate of potassium took place. An examination of the fruit grown at Charlottesville, Va., and Sandusky, Ohio, showed minute crystals, varying in size and shape, lying in the soft cells just beneath the skin of the fruit. They were not present at any time in the pulp or in the compact portion of the flesh in which the seeds are contained.

The fact that many of the crystals found did not conform in type to crystals of the bitartrate prepared from pure cream of tartar made it doubtful as to whether potassium bitartrate was deposited or not. Analyses of 1912 and 1913 grapes of the Concord, Catawba, Niagara, Delaware, and Norton varieties, however, showed that while the juice pressed from the hulls was very low in tartaric acid and salts, the organic matter remaining in the hulls after pressure, although less than half as acid as the pulp, is rich in tartaric acid and cream of tartar, in these regards nearly equaling the percentage found in the juicy pulp. The results made it obvious that the hulls, if pressed dry, would still retain the crystals mentioned and their presence was actually demonstrated with the microscope.

Further details of the investigation will be reported upon later.

The seeds and seed oil of bilberries and cranberries, A. DIEDRICHS (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 24 (1912), No. 9, pp. 575–580).—The weight of 1,000 cleaned seeds from the bilberry (*Vaccinium myrtillus*) is on the average 275 mg. The chemical composition of the seed calculated to dry substance was as follows: Protein 19.16 per cent, ether extract 33.25, crude fiber and nitrogen-free extract 45.81, and ash 1.78 per cent.

The oil extracted from the seeds was fluid at ordinary temperatures, was of a slight greenish-yellow color, and it had a pleasant taste. After standing

for a few days at room temperature, a sediment of stearin flakes was deposited. The constants of the oil were as follows: Specific gravity at 15° C., 0.9331; refraction at 40°, 71.2; at 25°, 79.8; iodine number 167.2; saponification number 190.4; Hehner number 95.72; degree of acidity 6.8; free oleic acid 1.92 per cent; Reichert-Meissl number 0.66; Polenske number 0.3; Baudouin reaction, negative; Halphen reaction, negative; and Bellier reaction, positive. The figures given by the fatty acids were for refraction at 40°, 57.3; iodine number 177.3; saponification number 200.7; and middle molecular weight 278. The hexabromide figure (Hehner and Mitchell) corresponded to that obtained for linseed oil, and linoleic acid was probably proven to be present in the oil.

The seeds of the mountain cranberry (*V. vitis idaea*) had the following chemical composition when calculated to dry substance: Protein 24.71 per cent, ether extract 32.03, crude fiber and nitrogen-free extract 41.01, and ash 2.25 per cent. The oil obtained from the seeds was light yellow in color and gave the following constants: Specific gravity at 15°, 0.9301; refraction at 25°, 75; at 40°, 83.4; iodine number 169.2; saponification number 190.1; Hehner number 95.7; acidity degree 3.45; free oleic acid 0.97 per cent; Reichert-Meissl number 0.55, Polenske number 0.3; Bellier reaction, positive; Baudouin reaction, negative; and Halphen reaction, negative. The fatty acids gave the following figures: Refraction at 40°, 60.4; iodine number 178.6; middle molecular weight 281; and saponification number 195.8. Linoleic acid was present. The weight of 1,000 seeds was 262 mg.

The hemagglutinating and precipitating properties of the bean, E. C. SCHNEIDER (*Jour. Biol. Chem.*, 11 (1912), No. 1, pp. 47-59; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 3, pp. 66, 67).—The protein obtained from the Scarlet Runner bean contains a very active blood agglutinating agent. The protein of other beans contains less of this agglutinating substance. It is supposed to be a product of hydrolysis. The agglutinating substances were found to vanish gradually from the cotyledons and simultaneously with any nutrient material which might be stored up in the seed. Extracts made from the roots, stems, or leaves of the bean were found to have no agglutinating properties. If rabbit serum is added to the clear extract of the bean, a flocculent precipitate is obtained. The latter reaction does not always agree with the agglutinating properties and it seems to have some relation to the phaseolin of the bean.

The chemical composition of some fungi, E. WINTERSTEIN, C. REUTER, and R. KOROLEW (*Landw. Vers. Stat.*, 79-80 (1913), pp. 541-562).—In addition to the material on *Boletus edulis* fungi which has been noted previously (E. S. R., 28, p. 501), this article deals with autolyzing tests made with a paste of an edible mushroom (*Agaricus campestris*) containing when calculated on an air-dry basis 9.3 per cent of total nitrogen, of which 4.82 per cent is protein and chitin nitrogen, 0.73 per cent due to nitrogenous bases, and the remainder represents amino and other forms of nitrogen. A part of the fluid portion of the autolyzed mixture, shaken with kaolin and filtered through paper, contained, when calculated to dry substance, total nitrogen 11.06, protein nitrogen 0.67, nitrogen in the form of amino acids, etc. 8.16, basic nitrogen 1.63, and ammoniacal nitrogen 0.6 per cent.

The remaining portion of the autolyzate was extracted with chloroform, and from the chloroform extract a hydrochloride salt was prepared which physiologically resembled imidazoleethylamin. The substances yielded a precipitate with phosphomolybdic acid, potassium, bismuth iodide, phosphotungstic acid, and picric acid. The precipitate obtained with the latter substances finally became crystallized. A gold salt, corresponding to isoamylaminchloraurate ($C_5H_{11}NHAuCl_4$) was also obtained. Of the purine bases, guanine was probably present, and adenine, xanthine, and hypoxanthine were noted. So-called histidine,

arginin, and lysin fractions were also obtained. The arginin fraction seemed to contain several bases as well as trimethylhistidin. Arginin was prepared with much difficulty as a characteristic copper salt. From the lysin fraction cadaverin (pentamethylenediamin), putrescin, and probably lysin were obtained.

Some incomplete data on *Cantharellus cibarius* and *Craterellus cornucopioides* are reported. The quantitative results, however, show that with these 2 fungi an autolyzate can also be obtained which contains many nonprotein nitrogenous bodies.

On the basis of the results reported it is assumed that as a result of autolysis most of the proteins contained in fungi are split into simple crystalline cleavage products and also into higher complexes, peptones, and polypeptids. The authors intend to isolate various enzymes from the fungi described, and it is believed that the enzymes present in fungi produce from the protein substances materials from which some of the phanerogamic plants obtain their nourishment. Other products formed by the same agency are probably absorbed by the humin substances present in the soil.

About the behavior of fungi (*Aspergillus niger* and *Penicillium crustaceum*) toward phytin, M. A. JEGOROFF (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 82 (1912), No. 3-4, pp. 231-242).—*A. niger* and *P. crustaceum*, when grown in solutions of phytin previously sterilized, cleave the latter with the production of inorganic phosphoric acid. No cleavage was noted when the sterile phytin solution was incubated alone. It was not possible to determine whether the fungi assimilated the phosphoric acid directly or indirectly, except to say that the phytin is a good source of phosphorus for these fungi.

The best development of the fungi was on the peptone and saccharose solution, or on either saccharose or glycerin. Peptone alone gave relatively unsatisfactory results. When various phytin preparations were compared, no differences were noted with the exception of hemp phytin, which gave a low yield.

Citric acid formation from glycerin by fungi, C. WEHMER (*Chem. Ztg.*, 37 (1913), No. 4, pp. 37-39).—It was found, in addition to the fact that glycerin serves as a source of carbon for the citromyces, that it may also be changed into citric acid. Calcium citrate was prepared to quite an extent from a culture fluid which contained, besides glycerin and the fungus, ammonium nitrate, potassium phosphate, and magnesium sulphate. The inoculations were made with spores from the fungus obtained from 2 sources, (a) isolated from an oxalic acid solution, and (b) was found in a fluid containing 0.5 per cent of free sulphuric acid and used for the hydrolysis of cotton. No acidification of the medium (free acid) takes place during the process, even when no calcium carbonate is present. The same is true when either sucrose, lactose, mannit, xylose, or arabinose displace the glycerin in the culture medium. In the case of glycerin other substances are formed besides citric acid, some of which reduce Fehling's solution.

The phenomenon whereby a fungus growing in a certain medium will split off appreciable amounts of citric acid when calcium is added still needs to be explained.

In addition to the cultural substances mentioned above, beer wort (16° B.), peptone with and without mineral substances, and alcohol in 5 and 10 per cent concentrations were tested. The two first-named substances were satisfactory while alcohol was toxic, even in a concentration of 5 per cent.

Amygdalase and amygdalinase in *Aspergillus niger* (*Sterigmatocystis nigra*), and several similar hypomycetes, H. JAVILLIER and MME. H. TCHERNOBOUTSKY (*Bul. Sci. Pharmacol.*, 20 (1913), No. 3, pp. 132-140, fig. 1; *abs. in Chem. Abs.*, 7 (1913), No. 13, pp. 2228, 2229).—The optimum acidity of the media for these enzymes is either 0.001 normal to helianthin, or neutral, and the

optimum temperature is about 57.5° C. The amount of either enzyme present varies with the age of the mold but amygdalase always predominates. The greatest enzymatic activity was noted in 4-day-old cultures. The ratio of the two enzymes varied widely in other molds, one enzyme being present in excess at one time, the other at another time.

Studies on enzyme action.—VI, The specificity of lipase action, K. G. FALK (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 5, pp. 616–624).—In this paper the action of methyl alcohol, ethyl alcohol, acetone, glycerol, and glucose on the activity of the lipase preparation was studied, and an explanation of the selective activity of lipases based upon the results obtained is given.

It is shown that "solutions of methyl alcohol, ethyl alcohol, and acetone exerted inhibiting actions on the hydrolysis of ethyl butyrate by a castor bean lipase preparation under comparable conditions, the amount of inhibition increasing with the concentration. Solutions of glucose and glycerol showed no inhibiting action except perhaps in the most concentrated solution. The view is suggested that simple esters exert an inhibiting action on lipase similar to that exerted by simple alcohols, and that higher esters (such as the glycerol esters) exert less inhibiting action similar to that exerted by glycerol.

"The lipolytic activity of the castor bean preparation was tested with solutions of methyl acetate, ethyl acetate, ethyl butyrate, and glyceryl triacetate (triacetin) of considerable ranges of concentration, and the results were correlated and explained by the aid of the theory outlined. Possible applications of the theory to the action of other hydrolyzing agents on esters compared with the action of lipase, to lipases of animal origin, and to the effect on the determination of the activity of lipase under various conditions of added substances, were mentioned. This theory, together with the specific actions of various groupings in the (presumably) protein molecule of lipase on the hydrolysis of esters as demonstrated [in the abstract below], will probably explain most, if not all, of the selective actions of the lipases. Finally, the use of triacetin as substrate for testing lipolytic activity is recommended."

Studies on enzyme action.—VII, A further study of the hydrolytic action of amino acids on esters, M. L. HAMLIN (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 5, pp. 624–632).—"Glycin, glutamic acid, and aspartic acid exert a varying lipolytic action on methyl, ethyl, glyceryl tri- and phenylacetates, ethyl butyrate, and ethyl and phenyl benzoates. If these be arranged in the order of decreasing amounts of hydrolysis, the order will be different in the 3 cases where the action is caused by water, by glycin, and by glutamic or aspartic acids. This indicates selective action. The effect of sodium chlorid, sodium sulphate, and magnesium sulphate in solutions from 0.2 to 2 normal is not marked or consistent enough to be important for this work. The hydrolytic action of solutions of glycin and acetic acid on methyl acetate and ethyl butyrate is less than that of corresponding solutions of acetic acid alone; this difference is proportionately much less with ethyl butyrate."

Comparative study of the cleavage of saccharose by various acids in the presence of yeast invertase, G. BERTRAND and M. and MME. ROSENBLATT (*Ann. Inst. Pasteur*, 26 (1912), No. 5, pp. 321–331; *abs. in Zentbl. Expt. Med.*, 2 (1912), No. 15, pp. 684, 685).—The hydrolyzing power of various organic and inorganic acids in the presence of invertase, and possibly also of many other soluble enzymes, does not depend entirely upon the hydrogen ion concentration. It is also dependent upon the nature of the acids, i. e., the anions.

Some properties of koji-diastrase, G. KITA (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 3, pp. 220–222).—"Though koji may contain 2 different saccharifying enzymes, viz, amylase and glucase, the total quantity of the glucose in a saccharified solution could not be produced from maltose by the action of glucase

alone; hence koji must contain some other kind of diastase which produces glucose directly from starch without the aid of glucase. Common salt has a protecting action on koji-diastase under heating but not on malt-diastase, while Na_2HPO_4 , asparagin, and H_2SO_4 impair its activity more quickly. The inhibitory action of salt on koji-diastase has a certain relation to the concentration of diastase. In a dilute enzymic solution it is very strong but not in a concentrated enzymic solution. It is therefore necessary in every case to note the concentration of diastase when we consider the influence of some salt upon it. The activity of koji-diastase is conserved in brine for a long period."

The determination of nitrogen in organic substances, HERZFELD (*Pharm. Ztg.*, 57 (1912), No. 97, pp. 979, 980; *abs. in Chem. Ztg.*, 37 (1913), No. 14, *Repert.*, p. 58).—The organic material is treated with metallic potassium, taken up with water, ferrous sulphate added, heated gently, and filtered. A contact test is then made with a slightly acidified (HCl) ferric chlorid solution. At the juncture of the two fluids a blue coloration appears if nitrogen is present.

The colloid matter of clay and its measurement, H. E. ASHLEY (*U. S. Geol. Survey Bul.* 388 (1909), pp. 65, pl. 1, figs. 9).—In this paper clay is defined as a mixture of granular matter and a colloidal gel. The sources of the colloidal matters are organic and inorganic substances. The organic source resembles peat, while the inorganic is principally colloidal silicates and silicic acid, and less commonly alumina and ferric oxid.

Adsorption, which is the property that colloids have of taking up other substances out of a solution or suspension, may in most cases be represented by exact equations. The plasticity of a clay may be measured approximately by the adsorption of a dye. "The plasticity, taken as the product of the deformability by the force resisting deformation, reduces to the expression $\frac{C \times B}{A}$,

where C is the measure of colloids present, B is the cast air shrinkage, and A is the Jackson-Purdy surface factor.

"The dye test supplies a measure of the efficiency of grinding in increasing the plasticity of a fire clay. Questions that call for further study are the possible finding of a better dye than malachite green, the disturbing influence of minerals and salts in clays, and the formulation of a field test for plasticity."

About the determination of colloid substances in the soil, ROHLAND (*Landw. Jahrb.*, 42 (1912), No. 2, pp. 329, 330).—It is stated that the method described above, with some modifications, can eventually be employed for determining the colloids in the soil. The colloids as such in the soil regulate the passage of water and nutrient material to the plant and retain deleterious substances.

A contribution to the estimation of colloids in soils, I. M. GÓESKI (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 11, pp. 1201-1216, figs. 2).—It was found that crystal violet can be used as an adsorption dye for colloidal substances. It was strongly adsorbed by soils, and when brought into contact with soils does not alter its shade, which is considered an important advantage. The estimation of the dye was made colorimetrically by the König, Hasenbäumer, and Hassler methods. Some preliminary experiments conducted in regard to the behavior of crystal violet toward ferric and aluminum hydroxid showed that crystal violet was not adsorbed by either substance.

In a chemical study of van Bemmelen's method 3 different kinds of soils were used. The adsorption capacity of crystal violet was measured with the 3 soils, and proved Freundlich's equation correct. A comparison of the van Bemmelen and the staining methods seemed to show that a parallelism exists between them.

Soil carbonates.—A new method of determination, W. H. MACINTIRE and L. G. WILLIS (*Tennessee Sta. Bul. 100 (1913), pp. 83–97, figs. 2*).—The purpose of this investigation was to determine (1) the mineral acid least active upon soil organic matter in the estimation of carbonates in soils, (2) the concentration of the acid which would be best suited to all occurrences in light or heavily limed soils, and (3) whether the determination could be made with the ordinary laboratory equipment without the application of heat.

In other work the senior author has used phosphoric acid in lieu of hydrochloric acid for the estimation of soil carbonates. In the work now reported a comparative study was made of sulphuric, hydrochloric, and phosphoric acids, all being tested in three strengths for this purpose. The soil used was a fairly fertile loam of marked acidity with a carbon dioxid content of 0.0196 per cent.

Phosphoric acid was found the least active toward soil organic matter. Sulphuric acid was the most active in this respect.

Accordingly the activity of a 1:15 solution of phosphoric acid toward the organic matter contained in an original loam soil was compared with the action on the carbonaceous material in the same soil subsequent to treatment with a 1 per cent solution of hydrochloric acid and carbonated water to remove any carbonates which might be present. The data show that boiling with acid gives practically identical results on an acid soil both before and after elimination of carbonates. Boiling an untreated acid soil with carbon dioxid-free distilled water also showed an evolution of carbon dioxid. "This shows either action of heat upon the soil organic matter or reaction between minute localized occurrences of soil acids and carbonates."

The Marr method (E. S. R., 22, p. 511) was studied with boiling and at room temperature, except that instead of sulphuric acid phosphoric acid was used on a soil in which the carbonates were removed by cold digestion with 1 per cent hydrochloric acid. "The results show considerably less action on organic matter at 50° C. than that effected by boiling, but appreciably more than at room temperature. The same results were also found in the case of well-rotted barnyard manure and of barnyard soil. The addition of 48 tons per acre of manure was found to cause no increase in carbon dioxid evolution by treatment with one-fifteenth phosphoric acid in the cold." "Phosphoric acid 1:15 at room temperature liberates all of the carbon dioxid from calcium carbonate and magnesium carbonate in soils, and the carbon dioxid evolved can be collected by aspiration with suction, either gravimetrically or volumetrically."

"The following method . . . has given entire satisfaction, having been used upon 135 soil samples which were under absolute laboratory control and covering light and heavy occurrences of carbon dioxid. Where evolution of carbon dioxid is not greater than 0.2 gm., 50 gm. of soil may be used, the amount of soil for the charge being decreased with an increasing percentage of carbon dioxid. The evolution is kept to this amount in order that the soda-lime tubes may be effective for more determinations. A separatory funnel connected with purifying apparatus leads through a 2-holed rubber stopper to the bottom of a 300 cc. Erlenmeyer flask. Through the second hole is inserted a bulb tube leading to 2 purifying bottles containing concentrated sulphuric acid. To the second acid bottle is attached a U tube containing soda lime and this is attached to a tube containing pumice stone saturated with concentrated sulphuric acid. . . . If volumetric determinations be desired, a Folin absorption tube or a tower containing glass beads may be used. After purifying the atmosphere of the apparatus, 60 to 100 cc. of phosphoric acid 1:15, carbon dioxid-free, is added through the funnel and the carbon dioxid drawn off at a very slow rate, with constant agitation, for 10 minutes. The second 10 minutes the rate is slightly increased, and during the third 10-minute period purified air is drawn

fairly rapidly through the system. Slight vacuum should be maintained. The essentials of the method are very slow aspiration at first, constant agitation, and slight vacuum."

If finely ground, limestone and dolomite can be examined for carbonic acid by the method with or without soil, under the above conditions. Dilute phosphoric acid in the cold is not appreciably active upon ferrous carbonate and but slightly so on manganese carbonate.

"In comparative carbon dioxid studies, a blank should be run upon the soil subsequent to its being freed of carbonates, and a correction made for the action of the acid on organic matter."

A bibliography is appended.

Examination of artificial fertilizers (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 7, pp. 850-886).—The methods included deal with the collection and preparation of samples; examination of fertilizers containing (a) phosphoric acid, (b) potassium, (c) nitrogen, and (d) lime; general methods for moisture; fine powder in Thomas slag powder; perchlorate in saltpeter; sulphocyanid in ammonium sulphate; lime and magnesia; sulphuric acid; iron and aluminum oxids; calcium sulphate; carbon dioxid; and the chloroform extract of bone meal. In addition to limits of error and the methods of reporting results are discussed.

In the appendix the preparation of the reagents is described, and a table is given for calculating phosphoric acid (P_2O_5) from magnesium pyrophosphate and potassium from potassium perchlorate.

Application of the microscope to the analysis of fertilizers, E. COLLIN (*Ann. Falsif.*, 6 (1913), No. 51, pp. 14-24, figs. 9).—This deals with the histologic features of the various organic substances which go to make up fertilizers. Especially considered are dried blood, powdered meat, insect debris, horny material, tannery waste (hides), waste hair, silk, wool, feathers, peat, and charcoal.

In regard to the determination of water-soluble phosphoric acid in superphosphates, F. PILZ (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 11, pp. 1238-1244).—The method originally adopted by the Austrian Association of Agricultural Experiment Stations consists of placing 20 gm. of superphosphate (or 10 gm. of double superphosphate) in a Stohmann liter flask with about 800 cc. of distilled water and shaking in a rotary apparatus (30 or 40 revolutions per minute) for one-half hour at room temperature. The mixture is then made up to the mark, shaken thoroughly, and filtered through a dry folded filter into a dry glass. By filling up the flask before rotation higher results are obtained, and this change has been adopted by the association.

Soluble silicic acid in Thomas slag powder and its influence upon the determination of citric acid-soluble phosphoric acid, M. POPP ET AL. (*Landw. Vers. Stat.*, 79-80 (1913), pp. 229-278).—A detailed account of material previously reported from other sources (E. S. R., 29, p. 410).

The determination of citric acid-soluble phosphoric acid in Thomas slag powder, W. SIMMERMACHER (*Chem. Ztg.*, 37 (1913), No. 15, pp. 145, 146; *abs. in Chem. Abs.*, 7 (1913), No. 13, p. 2278).—A review of methods and a discussion of Popp's method (see above).

The detection of alum in bread, J. R. N. VAN KREGTEN (*Chem. Weekbl.*, 10 (1913), No. 3, pp. 58-60; *abs. in Chem. Abs.*, 7 (1913), No. 13, p. 2262).—In addition to examining the ash, 2 reactions must be used. One of these is with tincture of hematoxylin (logwood); the other, which utilizes alizarin, must be modified for use with bread. Both reactions are given in the *Codex Alimentarius*.

Detection and estimation of the xanthin bases in cocoa, tea, coffee, and their derivatives, S. CAMILLA and C. PERTUSI (*Abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 601, II, p. 1111; *Jour. Soc. Chem. Indus.*, 31 (1912), No. 22, pp. 1002).—Small amounts of xanthin bases can be detected with potassium permanganate and potassium hydroxid in an aqueous solution wherein they form carbylamins. For estimating the xanthin bases, the following procedure is recommended:

Ten gm. of chocolate or cocoa is boiled for one-half hour with 150 cc. of water and 50 cc. of normal sulphuric acid solution, made up to 500 cc. with water, and then filtered hot. One-half of the filtrate is neutralized with magnesium oxid, concentrate to about 80 cc. on the water bath, acidify with dilute sulphuric acid, and extract with carbon tetrachlorid for from 2 to 3 hours. The extract, which contains the caffein, small amounts of theobromin, and fat, is after adding a little piece of paraffin, evaporated to dryness and the residue extracted with boiling water acidified with sulphuric acid. The solution is filtered and added to the remaining half of the original extract, and the whole evaporated to dryness with 5 gm. of magnesium oxid. The residue is extracted with boiling chloroform 4 or 5 times, using 100 cc. of solvent each time. The chloroform solution is then evaporated.

Tea and coffee products can be dealt with by a similar process.

The Babcock test with special reference to testing cream, H. E. Ross and T. J. MCINERNEY (*New York Cornell Sta. Bul.* 337 (1913), pp. 27-47, figs. 12).—This gives specific directions for performing the Babcock test for fat in milk, cream, skim milk, butter, cheese, sour milk, and churned milk, with some results of experiments.

In those which were made for the purpose of determining the effect of temperature on the fat column of a whole-milk bottle it was shown that "the fat column in a whole-milk bottle is not large enough to be greatly affected by temperature unless it is extremely hot or cold."

In testing skim milk it is necessary to use a special bottle, extra acid, and to whirl for a longer period of time in order to get proper results. Frozen milk should be melted, but in melting the ice no temperature above 85° F. should be used. Milk allowed to stand a time before freezing will show a high content of fat in the ice, while a milk agitated while freezing will show a greater quantity of fat in the liquid part.

For testing cream better results may be obtained by weighing the sample than by measuring it. In the experiments a difference of 0.5 to 4.5 per cent was noted between the two. It is advisable to immerse the cream bottle with its contents, after treatment with acid, in a water bath at 150° and in such a manner that the fat column is below the surface of the water. The length of time necessary for the fat column to reach the temperature of the bath varied in the experiments from 2 to 4 minutes. The use of about 0.5 cc. of glymol (white mineral oil) colored with alkanet is recommended in order to facilitate the reading of the fat column. This removes the meniscus and makes a sharper line of demarcation between the fat column and the added substance.

When the chemical method (ether extraction) is compared with the Babcock method and the meniscus is removed with glymol, "the Babcock method will compare very favorably for all practical purposes with the chemical method when read at a temperature between 140 and 150°. Sixty-four experiments were performed, both Babcock and chemical, and of that number there were 35 that compared within 0.2 per cent. The cream bottles are graduated only as fine as 0.5 per cent; therefore it may be concluded that in this number of experiments there were only 8 that varied more than 0.5 per cent."

The kinetics of the inversion of sucrose by invertase, C. S. HUDSON (*Abs. in Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 25 (1912), Sects. I-IV, App., p. 375*).—"Measurements by the polariscopic method at 30° of the rate at which the enzym invertase, prepared from bottom yeast, hydrolyzes pure sucrose in aqueous solution under the conditions of slight acidity which cause the maximum enzymotic activity, show that the reaction deviates from the unimolecular order to a large extent in 14 per cent sugar solutions, but approaches agreement with this order as the dilution increases. As the concentration of sucrose increases about 14 per cent, the reaction again approaches this order, and in 50 and 60 per cent solutions the order is followed within the limits of experimental error."

Inversion of cane sugar solutions with ammonium chlorid, F. STROHMER and O. FALLADA (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 8 (1912), Sect. Va., pp. 85-92*).—A study was made for the purpose of determining the conditions under which cane sugar is hydrolyzed through the agency of ammonium chlorid. The amount of inversion was found to be dependent upon the amount of ammonium chlorid used, the temperature, and the time in which these were allowed to act. Owing to the variable results obtained for the sucrose, the authors do not believe that the method in its present condition can be used for analytical purposes.

Attempts were made with catalyzers, zinc dust, and platinum sponge for the purpose of accelerating the reaction, but with unsatisfactory results. Adding a small amount of acid did not seem to help matters. The greatest degree of inversion was obtained when 50 cc. of sugar solution containing 13.024 gm. of saccharose, with 30 cc. of saturated ammonium chlorid solution, were brought to the boiling point. The solution, however, was yellow, which points to a decomposition of invert sugar. When catalyzers were used, the maximum inversion was not immediately obtained and progressed long after the solution was made up to the mark at 20° C.

A peculiar increasing inversion was also noted after half-normal sugar solution was heated at 110° for three-quarters of an hour with 30 cc. of a slightly acidified saturated solution of ammonium chlorid. The inversion was complete 24 hours after filling to the mark at 20°, but the results were higher than those coming from hydrolyzed saccharose. Heating for a whole hour at the same temperature will produce about the same results within 2 hours after filling to the mark.

The results of neutralizing the acid were also studied.

Corrected inversion method according to Clerget, E. SAILLARD (*Jour. Fabric. Sucr., 54 (1913), No. 4; abs. in Chem. Ztg., 37 (1913), No. 14, Repert., p. 66*).—The method consists of dissolving 52 gm. of molasses in a 200 cc. flask, clarifying with from 10 to 20 cc. of lead acetate solution, filling to the mark with water, and filtering. The excess of lead is removed from 100 cc. of the filtrate with sulphurous or oxalic acid, neutralization effected with calcium carbonate or barium carbonate, some pure animal charcoal added, and filtered. To 50 cc. of this filtrate is added 50 cc. of a 6.85 per cent solution of sodium chlorid and the polarization determined. To another 50 cc. of the filtrate are added 25 cc. of water and 5 cc. of hydrochloric acid of 22° B. (2.15 gm. of hydrochloric acid in 100 cc.). This is inverted in the usual manner, neutralized with 20 cc. of a solution of pure sodium carbonate containing the equivalent of 5 cc. of hydrochloric acid, filtered, and the (inversion) polarization determined. If the inversion is complete, the method gives accurate results.

Decomposition of glutamates on heating in aqueous solution, and a new optically active nonsugar [and its influence in the double polarization

method of determining sucrose], V. STANĚK (*Ztschr. Zuckerindus. Böhmen*, 37 (1912), No. 1, pp. 1-17; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 20, p. 1001).—In the experiments solutions of potassium glutamate were heated in sealed tubes for periods varying from one-half to 24 hours and to temperatures from 90 to 250° C., when the rotation in the presence of basic lead acetate and hydrochloric acid was determined. Heating at a low temperature and for a comparatively short time almost destroyed the optical activity.

"On studying the products of decomposition thus obtained, it was found that levorotatory glutimic acid, $C_5H_7NO_3$, is formed at the lower temperatures, such in fact as are used in practice, but that above 200° the optically inactive isomerid of the same acid is almost exclusively proved. In presence of hydrochloric acid, even in the cold, it was noticed that the optically active isomerid gradually loses its levorotation and becomes dextrorotatory, finally, in fact, becoming hydrolyzed to glutamic acid hydrochlorid, $C_5H_9NO_4HCl$. This observation has an important bearing on the determination of sucrose by the double polarization method in beet products, and it is computed by the author that if only 3 per cent of the levorotatory glutimic acid be present in beet molasses, the error will be 0.9 per cent when the ordinary basic lead acetate direct reading is followed; but only about 0.05 per cent if the acid direct polarization, using hydrochloric acid and urea, be employed."

A revision of the hundred point of the saccharimeter, F. J. BATES and R. F. JACKSON (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York]*, 25 (1912), *Sects. I-Ve*, p. 517).—"For the purpose of checking the accuracy of saccharimetric analysis, the polarization of highly purified sugar solutions was measured. For the preparation of pure sucrose the method of crystallization from aqueous solutions after concentration in a vacuum boiling apparatus was developed. The sugar thus prepared did not differ essentially from that precipitated by alcohol. A study of the purified sugar showed the absence of ash and a negligible quantity of reducing substances.

"The experiments on reducing sugars showed the effect of sucrose on alkaline copper solutions and in the calculations this effect was taken into consideration. The velocities of caramelization of sugar at various temperatures were measured and a curve plotted indicating the length of time needed at each temperature to produce a quantity of caramel equivalent in reducing power to 0.01 per cent invert sugar. The data are for 79.5°, 1.8 hours; 66.6°, 10.9 hours; 50°, 107 hours; 39°, 478 hours.

"The results prove that caramelization occurs at comparatively low temperatures, the effect taking place spontaneously, if slowly, at laboratory temperatures. The allowable time of heating as determined by the caramelization curve was applied to moisture elimination. A combination of high temperature and high vacuum was relied upon to dry the sample. Solutions for polarization were prepared, both gravimetrically, by reference to density tables, and volumetrically. The specific rotation of the normal solution was measured on a precision polarimeter for wave length 546.1 and found to be 78.385° at 20° C. By the use of a quartz plate, which had been certified by the Physikalisch-Technische Reichsanstalt and the Bureau of Standards, the scale correction of a saccharimeter was found and the correction applied to the polarization of the normal sugar solutions. These latter read not 100° but 99.91. The Herzfeld-Schonrock standard was concluded to be in error. If so, the new conversion factor for $\lambda=589.25$ was computed to be 34.626, and that for $\lambda=546.1$ was 40.707."

About the determination of raffinose in the sugar beet, L. NOWAKOWSKI and J. MUSZYŃSKI (*Abs. in Centbl. Zuckerindus.*, 21 (1913), No. 48, p. 1748).—The methods used for determining raffinose at the present time depend upon

making a direct polarization and a polarization after inversion, and the results obtained are calculated by Herzfeld's method. The chemical method in which the raffinose is converted into mucic acid by oxidation with nitric acid does not give satisfactory results.

The purpose of this work was to elicit which of the methods used at the present time for determining sucrose in beets, i. e., alcoholic digestion and hot aqueous digestion, is the most satisfactory for estimating the amount of raffinose, and in what way lead subacetate affects its estimation. The hot aqueous digestion method was the method finally recommended. Where no lead subacetate or an insufficient amount was used some raffinose was detected, but when as much as 10 cc. of subacetate of lead solution to the normal weight was employed no raffinose was found. In some experiments in which raffinose was added, almost the same amount was noted in the final calculation. The conclusion is reached that there need be no fear of forming lead raffinates in the hot aqueous digestion method.

Examination of commercial starch (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 11, pp. 1217-1220).—The methods described are those adopted by the Austrian Association of Agricultural Experiment Stations, and are for the purpose of supplying means for the uniform judgment of starches, especially potato starch, according to the standard set up by the Vienna Stock Exchange. The methods include those for color, spreading power, detection of chlorin and inorganic acids, determination of water (indirect determination of the starch), determination of ash, inorganic loading materials, acidity, and the direct determination of starch.

Examination and judgment of vegetable tanning substances (*Ztschr. Landw. Versuchsw. Österr.*, 15 (1912), No. 9, pp. 1122-1146).—A discussion of methods and criterions for the valuation of vegetable tanning materials as adopted by the Austrian Association of Agricultural Experiment Stations. The determinations to be made on tannin barks are tannins, nontannins, and possibly moisture; in extracts, tannins, nontannins, insoluble substances, moisture, and possibly ash. The last constituent will give a clew as to whether the extract has been sulphited.

Determination of fat in feeds, with particular reference to shaking out with trichlorethylene in the cold, R. NEUMANN (*Landw. Vers. Stat.*, 79-80 (1913), pp. 701-736, fig. 1).—The results obtained from various feeds showed that trichlorethylene was satisfactory for estimating the fat, etc., in this class of material. It was only necessary to extract in the cold. When the material under examination contains much protein, e. g., meat, fish meal, or much fat, e. g., ajowan residues or millet polish meal, it must first be treated according to von Hissink's method. Sesame cake, when extracted for a long time with ether, yields nonfatty substances which are deposited in the extraction flask, but by shaking this material with trichlorethylene in the cold, these substances are not extracted.

Homemade cider vinegar, W. G. SACKETT (*Colorado Sta. Bul.* 192 (1913), pp. 3-15).—In this bulletin the use of waste apples is urged for the preparation of cider vinegar. The various steps in the process are described and emphasis is laid especially on the use of pure cultures of yeast and bacteria for this purpose. The cultures are supplied at a nominal cost by the station.

Pineapple vinegar, W. P. KELLEY (*Hawaii Sta. Rpt.* 1913, p. 34).—In the canning of pineapples there results an enormous waste of juice which amounts to hundreds of thousands of gallons per annum. Some of the juice is utilized for making sirup and, to a limited extent, for preparing bottled pineapple juice.

Attempts to convert the juice into vinegar with the rapid vinegar process were made but the results were not entirely satisfactory. "On an average the

vinegar obtained contained an acetic acid content of about 3.8 per cent, which is considerably below the legal standard. Occasionally it was possible to obtain vinegar of approximately 4.5 per cent." Difficulty was experienced in obtaining a good degree of alcoholic fermentation of the juice, as various other types of fermentation took place simultaneously with it.

The price obtained for the finished product did not warrant further investigation of this problem but it may be continued at some future date.

Utilization of waste oranges, W. V. CRUESS (*California Sta. Bul.* 244 (1914), pp. 157-170, figs. 2).—In addition to the material previously noted (E. S. R., 30, p. 316), this bulletin describes the preparation of orange vinegar and orange wine from waste oranges, and reports analyses thereof.

In preparing orange vinegar it is recommended that the juice before fermentation be treated with potassium metabisulphite. After standing for 24 hours the clear juice is drawn off and fermented with pure cultures of yeast. The finished juice is stored in well-filled, closed barrels or tanks until required for converting into vinegar.

"Strong vinegar equal in amount to about one-fourth the volume of the fermented juice should be added to the orange wine to prevent the growth of wine flowers and promote the development of the vinegar fermentation. The vinegar fermentation must take place in containers that allow a good surface of the vinegar to be exposed to the air. The vinegar may be cleared by filtering."

"Orange wine may be made by defecating the fresh juice after the addition of moderate amounts of potassium metabisulphite to prevent fermentation for a short time, fermenting the clear juice with pure yeast, and filtering the finished wine to clear it. This cleared wine may be turned into sparkling orange wine by the addition of a small amount of sugar and by subsequent fermentation in bottles."

METEOROLOGY—WATER.

The weather element in American climates, R. DEC. WARD (*Abs. in Science, n. ser.*, 39 (1914), No. 1003, p. 429).—An abstract of a paper read at the tenth annual meeting of the Association of American Geographers at Princeton, N. J. Since American climates are chiefly made of cyclonic weather and the distribution of meteorological elements in a cyclone is different in different parts of the country the author has undertaken to prepare regional cyclonic weather types for the United States.

The frostless period in Maryland and Delaware, O. L. FASSIG (*Abs. in Science, n. ser.*, 39 (1914), No. 1003, p. 429).—This is an abstract of a paper read at the tenth annual meeting of the Association of American Geographers at Princeton, N. J., in which it is shown that "the number of days (average of 20 years) between the last severe frost or freezing temperature in the spring and the first in the fall ranges from 130 days in the west to over 200 days in the immediate vicinity of Chesapeake Bay. For further study of plant growth as related to climatic conditions, phenological observations of similar plants in the same soil (transported) are to be undertaken at many points, each group being visited every 10 or 15 days."

Soil moisture and agricultural meteorology, J. B. GÈZE (*Jour. Agr. Prat.*, n. ser., 27 (1914), No. 9, pp. 272-274).—It is maintained in this article that it is very important from the standpoint of agricultural meteorology to note regularly the moisture conditions of the soil, and certain simple observations having this object in view are described, such as the appearance with reference to moisture of the surface soil, the flow of drains or shallow springs,

the flow of streams, and the color of the water. These observations to be of interest to agriculture must be accompanied by a precise knowledge of the physical character of the soil studied.

Is the earth drying up? J. W. GREGORY (*Geogr. Jour.*, 43 (1914), Nos. 2, pp. 148-172, figs. 3; 3, pp. 293-318).—The evidence bearing on this subject is summarized in this article from a great variety of sources and for various parts of the world.

The general conclusion is that "there have been many widespread climatic changes in late geologic times, while in historic times there has been no world-wide change of climate."

An extensive bibliography of the subject is appended.

Is South Africa drying up? R. VON GERNET (*Agr. Jour. Union So. Africa*, 7 (1914), No. 1, pp. 47-50).—The author maintains that South Africa has been undergoing a process of desiccation, not only for the last 30 or 40 years but for thousands of years. He states "that the water courses carry less water than of old, springs and spruits give out even before the water has been taken out for irrigation, soft rains of long duration are rare, instead of which we are getting torrential and short downpours doing a lot of harm by erosions while the water is running to waste."

This condition is attributed to slow geologic processes resulting in the uplift of the land and the more recent influences of deforestation. The construction of a system of dams and reservoirs to store flood waters is urged as a remedy for the unfavorable conditions.

Secular variation of precipitation in the United States, A. J. HENRY (*Bul. Amer. Geogr. Soc.*, 46 (1914), No. 3, pp. 192-201, figs. 3).—The available precipitation data for the past 40 or 50 years are summarized in tables and diagrams and are discussed with reference to the country as a whole and to various districts. The author concludes that the data lend "no color to the theory of a cycle in precipitation . . . but in practically every case confirm the conclusion that the occurrence of wet and dry years seems to be wholly fortuitous so far as the United States are concerned."

The observations are thought to show that the probability that heavy rains will occur in all parts of the country in one and the same year is very small. "On the other hand, diminished precipitation over great areas seems to occur with much greater frequency than increased precipitation. The tendency in nature, as shown by the summary of the last quarter of a century, seems to be toward years of lean rainfall, while years of fat rainfall seem to be due to an extraordinary deflection or disturbance in one or more of the dominant members of the atmospheric circulation." The figures make it clear in general that precipitation varies not only from year to year but also as between the different parts of the country.

The snowfall about the Great Lakes, C. F. BROOKS (*Abs. in Science*, n. ser., 39 (1914), No. 1003, pp. 429, 430).—This is an abstract of a paper read at the tenth annual meeting of the Association of American Geographers at Princeton, N. J. It is explained that "the snowfall in this region is heavy because of much moisture precipitated at low temperature by the many winter cyclones. On account of the cooling action of land on the prevailing west winds blowing across the lakes, the east shores get more snow than the west. Ice on the lakes, by diminishing evaporation, reduces the snowfall of the leeward shores. Thus the heaviest snowfall comes early in winter on the east shores, in marked contrast with the late winter maximum on the west shores."

Nitrogen and chlorin in rain and snow, G. H. WIESNER (*Chem. News*, 109 (1914), No. 2830, pp. 85-87).—The nitrogen and chlorin content of 22 samples of rain and 9 of snow collected at Mount Vernon, Iowa, from February 22 to

June 5, 1912, is reported. The average of free ammonia in snow was 3.35 parts per million, in rain 0.931 part per million; alluminoid ammonia in snow 3.84 parts, in rain 1.13 parts; nitrite nitrogen in snow 0.0021 part, in rain 0.0018 part; nitrate nitrogen in snow 0.19 part, in rain 0.15 part. The average of the chlorin in the rain and snow was about 4.8 parts per million. It is estimated that the total amount of nitrogen carried down to the soil in rain and snow during the period named was 6.27 lbs. per acre.

The sterilization of water by ultraviolet rays, A. SILBERMANN (*Ztschr. Hyg. u. Infektionskrank.*, 77 (1914), No. 2, pp. 189-216, fig. 1).—The general conclusion reached from the investigations here reported is that sterilization of drinking water by means of the quartz mercury vapor lamp is entirely practicable provided precautions are taken to insure the proper working of the apparatus. These precautions are set forth in some detail.

A bibliography of references to the literature of the subject is given.

Metropolitan sewage farm, A. M. LAUGHTON (*Victorian Yearbook*, 33 (1912-13), pp. 260-264).—This is a brief account of the farm used in purification of the sewage of Melbourne, with data regarding its operation and efficiency.

The total area of this farm is 9.153 acres. The land is prepared for sewage disposal by division into paddocks of 20 acres each, seeded to alfalfa or perennial grasses (mainly prairie or rye grasses). "With the exception of a few hundred acres of lucern reserved for hay, the land is grazed with sheep, cattle, and horses, the practice being to keep the stock shifting from block to block to eat the feed down in front of the sewage water." The principal business is "the fattening of store sheep, but the grazing and farming operations are subservient to the main object of the farm, viz, the filtration of the equivalent of about 7.1 ft. of sewage per acre per annum."

The area actually under irrigation in 1911-12 was 4,932 acres; the area available for sewage disposal was 5,894 acres. The average daily quantity of sewage delivered to the farm was 31,066.653 gal. The revenue from grazing amounted to £15,245 (\$76,225). The net cost of sewage purification during the year was £8,736 (\$43,680) or 3.7 d. (7.5 cts.) per capita of population.

SOILS—FERTILIZERS.

Estimation of the surface of soils, J. A. HANLEY (*Jour. Agr. Sci. [England]*, 6 (1914), No. 1, pp. 58-62, fig. 1; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 4, p. 210).—Several methods of estimating the surface area of soils are noted and tests of the dye method described by Ashley (see p. 807) and by König, Hasenbäumer, and Hassler (*E. S. R.*, 26, p. 519) are reported.

Comparisons of the quantities of dye removed by sandy loam, loam, and clay loam soils from methyl violet dye solutions of 12 different strengths varying from 0.25 gm. to 3 gm. per liter showed that in all cases the dye absorbed increased rapidly with an increasing strength of dye solution up to a certain point when the soil appeared to become almost saturated, indicating "that if dye solution of one strength be used the three figures obtained can not be comparable. . . . To obtain relative values indicating the active surfaces of different soils it is necessary that each soil be brought into equilibrium with a solution of the same strength. . . . It is necessary to use . . . not the same strength of dye solution throughout but such a strength for each soil as will leave it when dyed in equilibrium with the same dye solution. . . . [Also] the relative values for different soils ought to be the same whatever the concentration of the final solution." Curves indicating the quantities of dye absorbed by the same soils "when in equilibrium with solutions of strengths varying by 0.0125 gm. per 100 cc. from 0.0125 to 0.125 gm. per 100 cc. . . . [show] that the values on the

lower parts of the curve where the dye solutions are weak vary considerably, but from 0.0375 per cent to 0.1125 per cent they are constant. . . . In actual experimental work, then, the equilibrium solution chosen should be one between 0.0375 and 0.1125 per cent; the most convenient is 0.05 per cent."

Study of the physical analysis of the fine particles of clay, A. MÜNTZ and H. GAUDECHON (*Ann. Inst. Nat. Agron., 2. ser., 12 (1913), No. 2, pp. 233-271, figs. 5*).—This is a more detailed account of investigations briefly reported elsewhere (*E. S. R., 30, p. 422*).

Soil investigations, J. W. AMES and E. W. GAITHER (*Ohio Sta. Bul. 261 (1913), pp. 449-512*).—Investigations on the composition of 126 calcareous and noncalcareous soils of Ohio are reported, special attention being directed to the phosphorus content as regards deficiency, availability, and combination.

The gradual loss of calcium carbonate from cultivated soil was illustrated by soils, originally of limestone formation but containing no calcium carbonate, in which the total calcium and magnesium and that soluble in fifth-normal nitric acid was greater than in soils overlying sandstone and shales. An acid soil receiving 12,000 lbs. of ground limestone in 1907 contained only 2,100 lbs. of calcium carbonate at the end of a 5-year rotation in 1912.

Sands, silts, and clays examined exhibited no marked differences in chemical composition, although the clays and clay loams generally contained less total silica and slightly more iron, alumina, and potassium. Calcareous soils contained less silica and more phosphorus and potassium than noncalcareous soils. Black clay loams of limestone origin contained more phosphorus and nitrogen than other soils analyzed. In most cases they contained calcium carbonate. The surface soil to a depth of 6 in. contained more phosphorus than the subsoils (6 to 36 in.) except in a few cases where the latter contained considerable calcium carbonate, and also more nitrogen and organic matter and fine particles. The total silica was generally largest in the surface soil while the silica soluble in fifth-normal nitric acid was usually greater in the subsoil. The total iron, alumina, and potassium were greater in the subsoil than in the surface soil. Soils containing no calcium carbonate contained more calcium and less magnesium in the surface than in the subsoil. Soils containing calcium carbonate contained more of both calcium and magnesium in the subsoil than in the surface soil, the calcium being in excess of the magnesium. Noncalcareous soils always contained more magnesium than calcium in the subsoil and generally more in the soil as a whole. All the soils examined contained more calcium than magnesium soluble in fifth-normal nitric acid.

The litmus paper test proved satisfactory as a qualitative test for the presence or absence of natural calcium carbonate in soils. "Of 126 surface soils examined for calcium carbonate and reaction, only five of those containing calcium carbonate reddened blue litmus paper. All the soils which gave an alkaline reaction with red litmus contained calcium carbonate. . . .

"The total phosphorus content of the soils studied varied from 0.3 per cent, or 6,000 lbs., per acre to 0.025 per cent, or 500 lbs., of phosphorus per acre in 6 in. of soil." Fourteen showed the presence of more than 0.1 per cent of total phosphorus. Soils containing calcium carbonate showed a larger supply of total phosphorus than the noncalcareous soils. The average phosphorus content of calcareous surface soils was 1,310 lbs. per acre, compared with 913 lbs. and 986 lbs. for the noncalcareous soils from the eastern and western sections of the State.

Black clay loams of limestone origin contained the most total phosphorus followed in order by the calcareous clays and clay loams. Alkaline soils containing natural calcium carbonate contained more available phosphorus (soluble in fifth-normal nitric acid) than acid soils. Calcareous sands and sandy

loams had a larger proportion (30 per cent) of their total phosphorus available than did silts and clays. The noncalcareous sands and sandy loams contained approximately the same amount of available phosphorus as the calcareous silts and clays. The calcareous black clay loams contained more available phosphorus than any of the other classes of soils, except the calcareous sands and sandy loams. The noncalcareous silts and silt loams and acid clays and clay loams were deficient in available phosphorus.

The analytical methods employed are outlined.

The red clay soil of Porto Rico, P. L. GILE and C. N. AGETON (*Porto Rico Sta. Bul. 14 (1914), pp. 24, pl. 1*).—This bulletin reports chemical studies and fertilizer experiments with the red clay soil, which is one of the most extensive soil types of Porto Rico. The soil is a fairly heavy clay underlain by an impervious subsoil, and requires good cultivation and drainage to be productive. It is characterized chemically by a high content of iron and aluminum, moderate amounts of nitrogen, phosphoric acid, and potash, and no carbonates. It is almost uniformly acid and frequently low in organic matter.

The soil is used chiefly for the production of coffee and sugar cane, and where it has been for a long time continuously in cane certain areas have become sick or tired and do not respond to fertilizers or superficial disinfection.

Fertilizer experiments carried on with sugar cane showed, however, that the normal soil is benefited by liming and fertilizers, and that nitrogen is the constituent most needed and probably increases the yield as much as a complete fertilizer. The cause of the unproductiveness of the sick soils was not determined.

Soils, G. AUCHINLECK (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Grenada, 1912-13, pp. 11-14*).—Physical analyses and data obtained by determinations of shrinkage and friability (E. S. R., 27, p. 120) of red, black, and gray soils originating from the weathering of lava and from the deposition of volcanic ash, mud, sand, or gravel are reported. The red soils are heavier than the black and the water content when air-dried is higher. "The gray soil is lightest of all, probably containing a larger amount of unweathered fragments."

Studies of meteoric waters, soil, and air at the observation stations of the Charcot expedition, A. MÜNTZ and E. LAINÉ (*Ann. Inst. Nat. Agron., 2. ser., 12 (1913), No. 2, pp. 179-231, figs. 7*).—The results reported in part 1 of this article, relating to nitrates and ammonia in meteoric waters, have already been noted from another source (E. S. R., 26, p. 515). The second part relates to unsuccessful attempts to isolate active nitrifying organisms from samples of debris collected from icebergs, it being impossible to obtain samples of true soil in the antarctic regions in which these observations were made. The third part reports examinations showing that the carbon dioxide content of the air of the antarctic region is decidedly smaller than that of temperate or tropical regions, the average found being about 2 parts per 10,000 parts of air. The oxygen content was found to be about the same as that of other regions.

The nitrifying efficiency of certain Colorado soils, W. G. SACKETT (*Colorado Sta. Bul. 193 (1914), pp. 3-43, figs. 3*).—Continuing his investigations into the causes of the excessive accumulation of nitrates in Colorado soils (E. S. R., 28, p. 31), the author made a detailed study of the nitrifying efficiency of these so-called "niter" soils as well as of soils from various places outside of the State. The term "nitrifying efficiency" is used in this connection "to denote not only the presence of the nitrifying organisms in the soil which are capable of exercising their specific function under favorable conditions (nitrifying power) but also the suitability of the soil as a medium in which the process of nitrification may proceed advantageously (nitrifying capacity)."

The conclusions reached are in brief as follows:

"Many cultivated soils of Colorado contain a vigorous nitrifying flora capable of transforming ammonical nitrogen into nitrate nitrogen. Both . . . normal soils and those in the incipient stage of the niter trouble possess this power in a very marked degree.

"Compared with soils from twenty-two other localities outside of the State, the Colorado soils examined are very superior in nitrifying efficiency. The nitrifying efficiency of Colorado soils bears an inverse relation to that of the foreign soils when referred to ammonium sulphate, ammonium carbonate, and dried blood as the nitrifiable substances. Colorado soils produced their highest average grains in nitric nitrogen from $(\text{NH}_4)_2\text{SO}_4$, the next largest from $(\text{NH}_4)_2\text{CO}_3$, and the lowest from dried blood. The foreign soils produced their largest average yields in exactly the reverse order. The nitrifying flora of the Colorado soils is distinct from that found in the majority of the foreign samples; it is either made up of entirely different organisms, or, if the same organisms, they behave like different strains.

"Excessive nitrates do not appear to interfere seriously with nitrification provided the chlorin is low. Excessive chlorin, with or without excessive nitrates, inhibits nitrification. Active nitrification takes place in the brown crust from the niter spots provided the chlorin is not excessive. The sample of raw adobe clay examined was deficient in nitrifying efficiency.

"The results of this study together with those of . . . two previous investigations justify the position that the excessive nitrates present in certain Colorado soils have resulted from the combined action of nitrogen-fixing, ammonifying, and nitrifying organisms."

An examination of some more productive and some less productive sections of a field, T. L. LYON, J. A. BIZZELL, and H. J. CONN (*New York Cornell Sta. Bul.* 338 (1913), pp. 51-115, figs. 12).—This bulletin reports physical and chemical examinations of the soils of productive and unproductive sections of the same field as well as studies of the bacterial flora of the soils.

Aeration increased, temporarily, the formation of nitrates and the productiveness of the poorer soil beyond that of the better. When the whole area was divided into small plats and cropped with millet for four years, there was a fairly constant relation in the yields of both productive and unproductive plats.

Neither type of plat was distributed with any definite relation to the topography of the area. Mechanical analyses of the soils showed that the texture underwent a gradual change from the upper to the lower part of the area, but there was no constant relation between the productiveness of the plats and their mechanical composition, and chemical analyses showed no great difference in the inorganic constituents.

The soils in the lower yielding plats were more compact than those in the higher yielding plats. "The more compact condition of the soil was less favorable to the formation of nitrates, and thus the qualities of productiveness, compactness, and rate of formation of nitrates are correlated." It is therefore concluded "that a too compact condition of the soil is the cause of the lessened productiveness of certain small sections of this soil for the growth of certain crops."

Conclusions of a general nature from the studies of the bacterial flora of these soils are as follows: The flora of soil is quite different from that of other natural media, consisting primarily of strict aerobes that do not produce spores, the majority of which liquefy gelatin very slowly and grow but poorly in the ordinary bacteriological media. Certain types of bacteria may occur throughout the year, growing in winter and in summer alike, while others grow

for short periods only. There is an intimate connection between the moisture content and the numbers of bacteria, the most striking exception being in winter when the germ content increases if the soil is well frozen, but decreases after a thaw.

In comparing the productive and unproductive plats, no type of bacteria found frequently in one soil was lacking in the other, and during the winter the total numbers of bacteria were higher in the more compact and less productive soil. The quantitative difference between the two soils lay wholly in the group of slow-growing organisms, and rapid liquefiers were often fewer in the less productive soil.

"At the end of the experiment the relative numbers of liquefiers had decreased and those of slow growers had increased in the less productive plat; while in the other plat this tendency had been almost unnoticeable."

A classification of the organisms and a bibliography of related works are appended.

The rational improvement of Cumberland Plateau soils, C. A. MOORE (Tennessee Sta. Bul. 101 (1913), pp. 99-138, figs. 6).—This bulletin, a continuation of work previously reported (E. S. R., 26, p. 422), points out the special plant food needs of the Cumberland Plateau soils which are mainly fine sandy loams deficient in lime and phosphoric acid, and reports 6 years' experiments to determine as far as possible, how much fertilizer to use on different crops in order to get the best practical results. Acid phosphate, muriate of potash, sodium nitrate, and cotton-seed meal are recommended as being the most profitable sources of plant food for general use. The importance of green manuring, soil inoculation, and crop rotation is pointed out as is also the relation of the potato crop to soil improvement.

The results of crop fertilization experiments were as follows: Fertilization of potatoes with 1,500 lbs. per acre of a mixture of 1, 6, and 8 parts, respectively, of muriate of potash, acid phosphate, and cotton-seed meal was on the average more profitable than 750 lbs. per acre of the same mixture. Sodium nitrate was only slightly more efficient for potatoes than cotton-seed meal. Fertilization of potatoes with manure showed the necessity of reinforcing the manure particularly with phosphoric acid. The best time for applying sodium nitrate to corn and potatoes was found to be at an early stage of growth for both crops. Acid phosphate alone in moderate quantity was as profitable for corn "as any other material or combination of materials of equal money value." A light manuring, supplemented by acid phosphate, is recommended for corn, and acid phosphate for a green manure or pasture crop which is to be followed by corn. Only a very light application of potash salt was needed for corn. The use of sodium nitrate was not generally profitable for corn. However, the results of tests of different fertilizer combinations "seems to justify the use of a complete fertilizer for corn on very poor soils like these."

On soils similar to the Plateau soils acid phosphate and sodium nitrate with a small amount of muriate of potash gave profitable results with millet. The general requirements for success with alfalfa, red, white, crimson, and alsike clovers, Lespedeza, melilotus, cowpeas, soy beans, Canadian field peas, spring oats, peanuts, small grains, grasses, buckwheat, and sorghum on these soils appear to be liming and phosphating, although some require soil inoculation, sodium nitrate, and manuring.

A list of crop rotations is suggested, including 5 and 4-year rotations for general farming and 3 and 4-year rotations for potato growing accompanied by a table to serve as a guide during the establishment of the 5-year general farming rotation.

The rational improvement of Highland Rim soils, C. A. MOOERS (*Tennessee Sta. Bul. 102 (1914), pp. 44, figs. 8*).—This bulletin deals in substantially the same manner with the Highland Rim soils as the bulletin noted above deals with the Cumberland Plateau soils, including some of the same field experiments with crops and fertilizers, and reaching practically the same conclusions as to the fertilizer requirements of potatoes, corn, and other crops on the soils of the two areas.

"The results of field experiments conducted in several different counties have demonstrated repeatedly that phosphoric acid is greatly needed by all the Rim soils, that liming is nearly always profitable, and that potash is often needed by the gray soils."

Experiments with corn following pasture and green manure crops on the very poor gray-colored soils of the area "afford a striking demonstration of the rapidity with which even a poor soil responds to proper treatment . . . and show both the marked increase in yield which may be brought about by the pasturing off of legumes, such as cowpeas and soy beans, and the great value of acid phosphate rightly used."

Fertilization of tobacco with 800 lbs. per acre of a mixture of potassium sulphate, acid phosphate, and cotton-seed meal 1:3:4 gave profitable results. Little difference was observed between sodium nitrate and cotton-seed meal as sources of nitrogen for tobacco. The use of farmyard manure increased the tobacco crop, but 6 tons of manure per acre together with 800 lbs. of the complete fertilizer noted above proved more profitable than either used alone. Tobacco was not directly benefited by liming.

A list of crop rotations is suggested including a 5-year rotation for general farming, a 3-year rotation for green manure and grain and one for general farming, and two 2-year rotations for pasturing hogs, accompanied by a table to serve as a practical guide during the establishment of the 5-year general farming rotation.

The applications of electricity to agriculture, T. T. BAKER (*Jour. Roy. Soc. Arts, 62 (1913), No. 3186, pp. 70-78, figs. 2; abs. in Jour. Soc. Chem. Indus., 33 (1914), No. 1, p. 35*).—An account is given of the application of high-tension electric currents to soil by means of overhead wires (particularly the Lodge-Newman system) for the purpose of increasing the yield of crops.

Reference is also made to experiments with waste material from radium manufacture mixed with the soil. It is stated that "good results have been obtained by mixing 1 part of radio-active material (2 mg. Ra per ton) with 10 of soil; with considerably larger quantities the yield was diminished and growth retarded. Some crops were benefited to a much greater degree than others. Good results have been obtained with radishes and wheat, but much less marked improvement with cress; in the case of radishes the sugar content also was markedly increased."

The relation of fertilizers to soil fertility, F. B. GUTHRIE (*Dept. Agr. N. S. Wales, Sci. Bul. 9 (1913), pp. 34*).—This is a short survey of present views on the subject, including especially summaries of the results of investigations relating to toxic substances in soils, sick soils, and catalytic fertilizers. A rather full bibliography of literature relating to catalytic fertilizers is given.

The use of commercial fertilizers, J. F. BARKER (*New York State Sta. Circ. 26 (1914), pp. 20*).—This circular presents in a popular way certain well established facts regarding the elements required for plant growth, the composition of the soil as related to the use of fertilizers, the teachings of the more carefully planned and conducted experiments with fertilizers which have been made in this country, and the home mixing of fertilizers.

The presentation of well grounded facts relating to fertilizers is considered by the author important at this time because of the "many conflicting theories and much unsound teaching on the subject of soil fertility," and because of his observation in New York "that, even at the present time, fertilizing practice is influenced more by the advertising agencies of the various fertilizer concerns than by the results of work at the agricultural experiment stations throughout the country."

Mixed applications of calcium cyanamid and sodium nitrate, P. BOLIN (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 79 (1913), pp. 8; *K. Landtbr. Akad. Handl. och Tidskr.*, 52 (1913), No. 4, pp. 276-281; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 9, pp. 1356-1358).—In experiments with oats calcium cyanamid was less effective than sodium nitrate, but mixtures of the two were more effective than either alone and were more economical than nitrate alone.

The possibility of using crude phosphates and limes containing silica as manures, T. PFEIFFER (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 9, pp. 1316-1321).—This article is substantially the same as one already noted (*E. S. R.*, 29, p. 520).

Ground limestone for soil improvement, J. F. BARKER (*New York State Sta. Circ.* 27 (1914), pp. 14).—Information on the subject drawn from various sources is presented in popular form in this circular which treats of solubility of limestone, function of carbonates in soils, chemistry of limes, comparative experiments with ground limestone and burned lime, limestone versus caustic lime, fineness of ground limestone, and methods of applying limestone. A list of companies in New York producing ground limestone or marl for agricultural use is appended.

Pennsylvania limestone and lime supplies, W. FEAR (*Pennsylvania Sta. Bul.* 127 (1913), pp. 71-106).—This is a compilation and brief discussion of analyses of limestones from the various deposits in the State of which 54 are sufficiently definite to have received distinguishing names. The limestone formations are classified in their geological order beginning with those of most recent age. A compilation of analyses of commercial lime products is also given.

Trials with molasses as a sugar-cane manure or fertilizer, and with chlorinated lime as a soil ameliorant, J. B. HARRISON and R. WARD (*Jour. Bd. Agr. Brit. Guiana*, 6 (1913), No. 3, pp. 123-126; *Internat. Sugar Jour.*, 15 (1913), No. 176, pp. 373-375; *abs. in Chem. Abs.*, 8 (1914), No. 4, p. 774).—In experiments in which diluted molasses was used at rates of 100, 200, and 300 gal. per acre the average results for 3 years showed a slight increase for plats treated with molasses, but this increase is attributed solely to the nitrogenous matter contained therein. In experiments in which 150 lbs. per acre of chlorinated lime was applied in solution to a stiff clay soil the yields on the treated plats were but slightly larger than those obtained on the untreated plats.

Trials with molasses as a sugar-cane manure, W. P. EBBELS (*Internat. Sugar Jour.*, 15 (1913), No. 177, p. 427; *abs. in Chem. Abs.*, 8 (1914), No. 4, p. 774).—Referring to the experiments noted above it is stated that the negative results were probably due to the fact that the molasses was not applied at the proper time, viz, three or four months before the cane was planted and in the holes made to receive the cane.

The fertilizing action of sulphur on grapes, V. VERMOEEL (*Bul. Soc. Nat. Agr. France*, 74 (1914), No. 1, pp. 48-51).—Marked benefit was derived from the use of sulphur (178.5 to 357 lbs. per acre), especially when applied in connection with manure. The effect of the sulphur decreased as the amount of manure applied diminished.

The action of manganese in soils, J. J. SKINNER, M. X. SULLIVAN, ET AL. (*U. S. Dept. Agr. Bul. 42 (1914), pp. 32*).—Previous investigations both by the Bureau of Soils and by others bearing on this subject are reviewed, and pot and field experiments as well as culture experiments with extracts of good and poor soils are reported.

It was found that manganese chlorid, sulphate, nitrate, carbonate, and dioxid had a stimulating effect on wheat grown in an unproductive sandy loam soil. The best results were obtained when the salts were applied in amounts furnishing from 5 to 50 parts of manganese per million of soil. When the maximum rate named was exceeded there was no corresponding increase in growth, and in some cases there were even harmful results. On productive loam the various salts of manganese had no stimulating effect.

With aqueous extracts of poor unproductive soils the manganese salts increased oxidation and growth. In the case of productive soils oxidation was increased but growth was decreased, the plants showing indications of excessive oxidation.

In a 5-year field test with wheat, rye, corn, cowpeas, and potatoes grown on an acid silty clay loam soil manganese sulphate used at the rate of 50 lbs. per acre had a harmful effect on all of the crops grown. Its addition decreased the oxidizing power of the soil, which at best was not very high. The acid condition of the soil was unfavorable to oxidation and catalysis, and the catalytic power was slightly, if at all, increased by the addition of manganese sulphate.

The general conclusion is "that manganese is not profitable as a soil treatment on soil of this nature in need of liming."

Commercial fertilizers: Inspection 1913, B. H. HITE and F. B. KUNST (*West Virginia Sta. Insp. Bul. 2 (1914), pp. 39*).—This bulletin gives the guaranteed and actual analyses of fertilizers inspected during 1913. The average composition of the fertilizers examined during the year was available phosphoric acid 10.46 per cent, potash 2.74, and nitrogen 0.46. The corresponding averages five years ago were 9, 2.5, and 0.41 per cent, respectively. The fertilizers of which analyses are reported in this bulletin are classified as low-grade if the total of available phosphoric acid, ammonia, and potash claimed in the guaranty falls below 12 per cent, high-grade if the sum is 14 per cent or over, and medium if between 12 and 14 per cent. Farmers are advised not to buy fertilizers containing less than 14 per cent of available plant food, including at least 1.65 per cent of nitrogen.

AGRICULTURAL BOTANY.

The chemical dynamics of living protoplasm, W. J. V. OSTERHOUT (*Abstr. in Science, n. ser., 39 (1914), No. 999, p. 292*).—The author claims that by measuring the electrical resistance of living tissues it is possible to follow the progress of reactions in protoplasm and that it is possible to apply van't Hoff's methods and formulas to protoplasm in its living and active condition.

As an example of the application a brief description is given of experiments with *Laminaria* in sodium chlorid solutions. From this experiment the author concludes that "since the effect of sodium chlorid is within wide limits completely reversible, without production of injury, the conception of chemical dynamics here developed applies not only to reactions which produce death, but also to reactions which involve no injury and which form a normal part of the activity of the cell." This conclusion, it is said, is confirmed by experiments with a variety of other substances.

The chemical behavior of inorganic nitrogenous plant food materials in sunlight, O. BAUDISCH (*Vierteljahrsschr. Naturf. Gesell. Zürich, 58 (1913), No. 1-2*,

pp. 10-14).—Noting briefly recent experiments of his own, the author concludes that from inorganic nitric compounds in sunshine in the presence of formaldehyde more complex nitrogen compounds are formed, this fact furnishing on the chemical side support for the view that assimilation of nitrates and nitrites is a photochemical process.

Contributions regarding the effect of manganese and aluminum on plant development, II, T. PFEIFFER and E. BLANCK (*Landw. Vers. Stat.*, 83 (1913), No. 3-4, pp. 257-281).—The authors, reporting further studies (E. S. R., 28, p. 328) state that manganese salts but slightly increased the production of dry substance in small grains, but that the organic substance was considerably increased. Aluminum sulphate in small quantities with small proportions of manganese sulphate showed only a slight stimulation of yield, while the addition of aluminum rapidly decreased the returns, exceeding manganese in this respect. These investigations are said not to have borne out the claim of Stoklasa (E. S. R., 25, p. 522) regarding the neutralization by aluminum of the injurious effects of the manganese salt.

Influence of metals on development of *Aspergillus niger* in Raulin's liquid, M. BORNAND (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 18-19, pp. 488-496, figs. 4).—It is stated, as a result of a study of *A. niger* in Raulin's fluid in contact with metallic platinum, aluminum, silver, copper, iron, tin, lead, zinc, and nickel, that the growth of this fungus is rather hindered than promoted by the presence of all but the first two, and that normal development is not shown after the substitution of iron and zinc for their salts used in Raulin's fluid.

A contribution to the theory of antagonism, W. J. V. OSTERHOUT (*Abs. in Science, n. ser.*, 39 (1914), No. 999, p. 292).—It is claimed that by means of electrical measurements of living tissues it is possible to predict which salts will antagonize each other when allowed to act upon these tissues.

The effect of antagonistic or balanced solutions containing sodium chlorid together with one of the chlorids of calcium, magnesium, potassium, strontium, ammonium, or copper, upon the growth of corn plants rooted in an artificial soil, J. S. CALDWELL (*Abs. in Science, n. ser.*, 39 (1914), No. 999, p. 293).—A preliminary account is given of experiments carried on with each of the 6 pairs of salts to determine their effect on plants grown in finely divided quartz. For each pair of salts 10 to 20 different concentrations were used, varying from the lowest concentration that inhibited development to a dilution so great as to be without effect upon the plants. In all cases results were measured by comparing the dry weights of the roots and tops taken separately, the cultures being allowed to grow under controlled conditions for 30 days.

Antagonism was observed between sodium and strontium at all molecular ratios between 10:1 and 20:1, and in all concentrations between those just permitting measurable development and those too dilute to have any discoverable effect, except that of root development. The effect of the additions of calcium to sodium was merely to decrease the characteristic physiological and morphological effects of sodium in a degree directly proportional to the amount added, the effect being one of dilution and not of antagonism.

In mixtures with copper, sodium served merely to dilute the copper salt, decreasing the toxic or stimulatory effect directly proportional to the amount added, but in no case annulling the effects of the copper salt.

Additions of magnesium to sodium in any proportions or at any concentrations were without effect upon the development of the aerial parts. In highly toxic concentrations mixtures in the ratio of 2:1 gave somewhat better development of roots, while in all stimulatory concentrations of 1:1 gave the best

dry weight of roots. Mixtures of sodium and potassium inhibited development of both roots and tops in all inhibitory or toxic concentrations to a markedly greater extent than did isosmotic solutions of the pure salts. In stimulatory concentrations the pure salts permitted greater and more normal development than mixtures. Sodium in any proportion decreased the stimulatory effect of potassium.

For mixtures of sodium with ammonium, highly toxic concentrations permitted slightly greater development when the two ions were present in the ratio of 1:1. For stimulatory concentrations the stimulating effect was decreased in mixtures, growth becoming better as the ratio of one ion to the other increased from 3:1 to 60:1.

The harmful action of distilled water, R. H. TRUE (*Abs. in Science, n. ser., 39 (1914), No. 999, pp. 295, 296*).—Attention is called to the injurious action of distilled water, the author stating that samples which show the highest resistance are in general more harmful to lupine roots than waters containing a large quantity of electrolytes. The primary cause of injury is said to be the extraction of electrolytes and perhaps of other substances as well. This is regarded as a special case of the general type of injury wrought on cells by unbalanced solutions. The distilled water seems to withdraw the material required for the maintenance of the efficient action of the protoplasmic limiting membranes, with the result that the permeability of the cells is increased and a further dissociation of the electrolytes from their combination in the proteids and other chemical structures of the cell ensues.

In a subsequent paper the author calls attention to the need of plant physiologists for a normal physiological solution in which to conduct their experiments.

Radio-activity and vegetation, M. VACHER (*Génie Rural, No. 49-50 (1913), pp. 8-12, figs. 4*).—This is a somewhat abridged form of an article previously noted (*E. S. R., 30, p. 29*) from another source.

The physiology of the rest period in potato tubers, C. O. APPLEMAN (*Abs. in Science, n. ser., 39 (1914), No. 999, p. 294*).—The author claims that the rest period of potato tubers is not firmly fixed and hereditary, as it may be eliminated by various agencies.

Biochemical study of after-ripening in the potato tuber, C. O. APPLEMAN (*Abs. in Science, n. ser., 39 (1914), No. 999, p. 294*).—Attention is called to the fact that under normal conditions potato tubers will not sprout for several weeks after harvest, or until certain changes have taken place in the buds or their immediate environment. These changes are spoken of as after-ripening.

In the author's experiment tubers were cut in half and analyses made separately of the seed and stem halves, with the view to detecting the chemical changes characteristic of after-ripening. The carbohydrate transformations were dependent entirely upon changing temperatures. Active diastase was present at all stages of the rest period and showed no increase during natural after-ripening. Protein, lipid, organic extractive, and inorganic phosphorus, calculated as total phosphorus, each remained constant up to the time of sprouting. It appears that after-ripening does not involve proteolysis or other changes in the various nitrogen combinations.

The metabolic changes involving the above substances as well as others are said to begin rather suddenly, are concurrent with sprouting, and are therefore not primary processes of after-ripening.

Metabolic changes in potato tubers during sprouting, C. O. APPLEMAN (*Abs. in Science, n. ser., 39 (1914), No. 999, pp. 293, 294*).—The author presented an account of investigations the practical application of which has been noted elsewhere (*E. S. R., 29, p. 230*).

It was found that under constant storage temperature starch was depleted while the reducing sugars showed a slight increase, the carbohydrate changes being more rapid in the stem end of the tubers. Both diastase and invertase activity was doubled, the increase being greater in the stem half of the potato. Catalase showed a marked increase, which was slightly greater in the juice from the seed end. The nitrogen of monamino acids and their amid derivatives increased, while that of the diamino acids and other organic bases and the water insoluble protein nitrogen decreased. The abundant water soluble protein nitrogen in the tubers showed a very slight increase during sprouting. Organic extractive and lipid phosphorus increased at the expense of protein and inorganic phosphorus. The increase in lipid phosphorus began earlier and increased more rapidly in the seed end. The decrease in inorganic phosphorus occurred in the seed end only. In many cases the metabolic activity was found greater in the stem half, although the sprouts were all borne on the seed end of the tuber.

Differential permeability, W. J. V. OSTERHOUT (*Abs. in Science, n. ser.*, 39 (1914), No. 999, p. 293).—Attention is called to the differences in permeability possessed by various kinds of surfaces in the cell, such as the plasma membrane, the vacuole-wall, the nuclear wall, the surface of the chromatophore, and the cell wall. The author suggests the term differential permeability as an appropriate designation of these phenomena.

Inefficacy of cultivation for destroying weed seeds, O. MUNERATI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), I, No. 2, pp. 120–126; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, pp. 661, 662).—The author concludes a briefer account of recent work (*E. S. R.*, 30, p. 332) by stating in substance that the age of weed seeds has usually much more to do with the time and percentage of germination than do such conditions as moisture and depth below the surface; that slow germinability favors persistence of weeds; that superficial or frequent working of the soil does not necessarily destroy many weed seeds; and that the only method that is certainly efficacious in checking propagation of harmful weeds is their destruction before the seeds ripen and fall to the ground.

Recent contributions on problems regarding mycorrhiza, J. PEKLO (*Ztschr. Gärungsphysiol.*, 2 (1913), No. 4, pp. 246–289; *abs. in Ztschr. Bot.*, 6 (1914), No. 3, pp. 293–295).—This is a detailed account of recent studies by the author and others on the cytology and physiology of fungal mycorrhiza in nutritive relation with pine and fir, more particularly as regards the assimilation of atmospheric nitrogen, which some are claimed to be able to accomplish.

The counting of protozoa in soil, J. KILLER (*Centbl. Bakt. [etc.]*, 2. Abt., 37 (1913), No. 17–21, pp. 521–524).—The author discusses methods of counting soil protozoa, emphasizing the proper procedure and precautionary measures for obtaining accurate results.

Tests of different concentrations of seven different nutritive solutions inoculated with different soil solutions showed that the chemical composition of the culture medium and the concentration of the nutritive solutions exerted a marked influence on the kind and powers of development of the soil protozoa. It is concluded that the values of all counting methods are limited and that a knowledge of the effect, intensity, and nature of the activity of the soil protozoa is much more important.

Studies of teratological phenomena in their relation to evolution and the problems of heredity.—I, **A study of certain floral abnormalities in Nicotiana and its bearing on theories of dominance**, O. E. WHITE (*Amer. Jour. Bot.*, 1 (1914), No. 1, pp. 23–36, figs. 4; *abs. in Science, n. ser.*, 39 (1914), No. 998, p. 255).—Studies are reported of races of *Nicotiana* showing petalody,

pistillody, and catacorolla which were crossed with normal plants. The data secured indicate that dominance and recessiveness are not in any way attributes of the factor or character in itself, but are the result of the factor expression plus the modifying influence of the environment.

Notes on root variation in some desert plants, W. A. CANNON (*Plant World*, 16 (1913), No. 12, pp. 323-341, figs. 4).—Reporting studies on a number of desert plants, the author states in substance that root systems of desert perennials may be roughly classed as generalized or specialized. The former, as in case of *Franseria dumosa*, are capable of greater variation than the latter, such as cacti. Under cultural (garden) conditions *Opuntia arbuscula* and *O. neoarbuscula* were not modified by an unaccustomed depth of soil and water, as were, however, *O. spinosior*, *O. viripara*, and *O. discata*. Variations were experimentally induced as to length of roots in a number of plants named, grown in tubes, the roots of all these showing increase in length.

FIELD CROPS.

Growing crops and plants by electricity, MISS E. C. DUDGEON (*London*, [1913], pp. VIII+36, figs. 12).—The author reviews briefly some work of other investigators on this subject and gives some results of her own experiments.

Potatoes grown under electrical influences in the field produced from 12 cwt. 12 lbs. to 2 tons 4 cwt. per acre more than those grown on the control plots. "It is also evident that some crops respond to the treatment better than others; in all the experiments there has been a distinct advance in the percentage of wheat, in potatoes the returns vary considerably, with a few exceptions leguminous plants are adversely affected, but a curious point in connection with these plants is that grown in rotation they have an opposite effect upon the soil to cereals."

Experiments with the mercury vapor lamp in the greenhouse on the germination of French beans, carrots, cauliflowers, lettuce, Maple peas, oats, barley, and wheat showed a shortening of the germination periods ranging from 5 to 20 days. Filbasket peas matured 3 days earlier under the mercury vapor lamp than in the control pots.

Experiments on the influence of electricity upon plant growth, W. SCHIKORRA (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 5 (1913), No. 5, pp. 403-411, fig. 1).—In this article the author discusses the work of other investigators and gives some results of his own experiments with pot cultures. The method of applying the electricity is fully described. The current, 35,000 to 40,000 volts, is taken from a machine and made to jump a distance of 15 cm. from a copper wire point suspended over each pot to an upright copper wire point in the center of the pot.

The results of connecting the suspended point with either the positive or negative pole showed an injurious effect of the current on rye and winter barley when applied during a period of from 16 to 20 days at intervals amounting to a total of from 42 to 51 hours. The decrease in yields amounted to from 11.3 to 14.8 per cent.

In another experiment in which the charge received by the pots was reduced, rye showed an increase of 0.4 per cent and winter barley an increase of 11.6 per cent in yield after a period of 70 days, during which the treatment occurred for a total of 243 hours. When the copper points in the pots were removed, barley showed an increase of 8.9 per cent and oats of 16.1 per cent in yield of dry matter over no treatment.

The experiments described above were carried on in an inclosed room. When the work was transferred to the open, the atmospheric moisture interfered with

uniform discharges and resulted in yields varying from 5.1 per cent increase to 16.6 per cent decrease over no treatment. In studying the effect of electrical discharges upon transpiration and evaporation it was found that when the discharge took place from points placed 13 cm. above a water surface, evaporation took place much more rapidly than from an untreated surface, ranging from 5 to 10 times greater.

Experiments in the application of electricity to crop production, J. H. PRIESTLEY (*Jour. Bd. Agr. [London]*, 20 (1913), No. 7, pp. 582-594, fig. 1).—In this article further work (E. S. R., 23, p. 326) is reported upon attempts to study the effect of electricity on growing crops. Some results of previous investigators are discussed, and methods employed in the author's experiments briefly described, in which wires carrying the current were stretched over the area to be tested.

It was found that because of the wind the effect of the electrical discharge was not confined to the area under the wires, and that control plats would have to be located at least 100 yds. distant. The yields of potatoes from the treated and the control plats were practically equal, but in further tests the treated area will be inclosed in wire netting to prevent the action of the wind.

Report of the agronomist, C. K. McCLELLAND (*Hawaii Sta. Rpt. 1913*, pp. 35-42).—It is noted that the results of rice experiments show the impossibility of producing rice in Hawaii equal in quality to that of Japan.

Cultural experiments with corn, small grains, grasses, forage crops, cotton, sorghums, sweet corn, and Irish potatoes, and the general field work of the substations at Waipio and Kula are also briefly noted. The new grasses most promising for hay and soiling crops are said to be Natal redbtop, Australian blue grass, Tunis grass, and Sudan grass.

[**Field crops work at the Glenwood substation**], **F. A. CLOWES** (*Hawaii Sta. Rpt. 1913*, pp. 52, 53).—Of 20 varieties of grasses tested the most promising were Para grass, Italian rye, Natal redbtop, *Paspalum dilatatum*, and rescue grass. Para grass yielded in 5 cuttings during 372 days at the rate of 70.7 tons of green fodder per acre. Large yields of green feed were also secured from oats sown from September to December. Notes on varieties and cultural tests with corn, sorghum, barley, soy beans, jack beans, and clovers are also given.

Experiments with leguminous plants, C. A. SAH2 (*Hawaii Sta. Rpt. 1913*, pp. 43-49, pl. 1).—This includes notes on cultural and variety tests of various legumes and descriptions of some new varieties in the tests, including *Stizolobium pachylobium*, soy beans, sword and jack beans, velvet beans, horse beans, asparagus beans, Sesbania, kulthi, *Dolichos lablab*, sunn hemp, stock or field peas, white navy beans, Lima beans, mungo beans, and a variety of Cuban peanut.

The Hawaiian method of brewing Japanese soy sauce and miso is described.

Botanical considerations affecting the care of grass land, R. G. STAPLEDON (*Jour. Bd. Agr. [London]*, 20 (1913), Nos. 5, pp. 393-399; 6, pp. 488-499).—The author presents the results of studying the botanical characteristics of grass land by determining the quality and quantity of the weed, leguminous, and gramineous flora, the ratio of valuable to useless grasses all the year round, "the condition of the useful plants in regard to the production of nutritious herbage, the nature of the aggregate root system of the pasture or meadow, the degree of productiveness of the several useful plants throughout the year, the quality and quantity of the moss flora throughout the year, and the factors affecting the foregoing considerations and their interrelations."

The 2 methods employed to determine the botanical constituents of a field were to count the plants in various areas of 6 by 6 in. or 1 by 1 ft. located in several parts of the field, both in the spring and late fall, and also to count the cut

herbage in the summer. To study the competitive relations of the root systems typical turf areas were lifted and the quantity of weed roots estimated.

The data as taken in various locations in England and also the care of grass land, including manuring and aeration, are discussed.

Pastures and pasture grasses for Utah, F. S. HARRIS (*Utah Sta. Circ. 15* (1913), pp. 35-42, pls. 2).—This describes 12 grasses and clovers suitable for pasture purposes in Utah, gives some seed mixtures, and directions for the planting and care of pastures.

Variety tests of field crops in Utah, F. S. HARRIS and J. C. HOGENSON (*Utah Sta. Bul. 131* (1914), pp. 319-346, pl. 1, fig. 1).—"This bulletin gives data on the yields of different varieties of wheat, oats, barley, corn, potatoes, and beans. The information was obtained from the following sources: (1) The station farms near Logan, (2) the dry-farm substation at Nephi, (3) cooperative tests with a number of good farmers in different parts of the State, and (4) correspondence with a large number of farmers. As a result of the tests it is impossible to say exactly what varieties are best, but with each crop there are a number of varieties that do well under almost all circumstances."

Division of cereals: Summary of results, 1913, C. E. SAUNDERS ET AL. (*Canada Expt. Farms Bul. 74* (1914), pp. 32).—Brief notes with some data on cereal variety tests at 15 experimental farms in Canada are reported.

Preparing land for grain crops on the prairies, J. H. GRISDALE (*Canada Expt. Farms Bul. 15, 2. ser.* (1913), pp. 23, figs. 7).—Methods of preparing land for crops in Saskatchewan, Alberta, and Manitoba with animal and tractor power are described in this summary of available data.

Experiments concerning the top-dressing of timothy and alfalfa, T. L. LYON and J. A. BIZZELL (*New York Cornell Sta. Bul. 339* (1913), figs. 4).—This continues work in rotation experiments, previously noted (*E. S. R.*, 21, p. 42; 23, p. 138), on a silty phase of Dunkirk clay loam in which "a series of field plats were subjected to a cropping rotation of timothy 3 years, corn, oats, and wheat each one year. Fertilizers or farm manure were applied to the timothy but not to any of the grain crops, different applications being used on different plats. The experiment has been conducted for 9 years.

"The results show that fertilization of the soil for timothy increases its productiveness for succeeding crops. The greatest benefit was derived by the corn crop, which immediately followed the timothy. The oat crop experienced the next greatest benefit, and the wheat the least.

"Tabulations of the financial gains demonstrate that the use of fairly large applications of fertilizers was profitable, resulting in as much as \$65 per acre net gain for the 6 years and giving a return of \$1.67 for every dollar invested in the fertilizer. Commercial fertilizers, while not superior to farm manure, were about equally effective. On grain crops commercial fertilizers are usually of less value than farm manure judiciously applied. This experiment indicates, therefore, that it is good practice to apply commercial fertilizers to timothy and thus save the farm manure for other crops.

"Alfalfa that had been growing for 6 years was laid off in plats, which were top-dressed with (1) farm manure, (2) acid phosphate, (3) acid phosphate and muriate of potash. All these treatments caused an increase in the yields of hay. Farm manure produced a financial loss; the other treatments resulted in monetary gains, acid phosphate applied singly being superior in this respect.

"Adjoining plats of land, on one of which alfalfa grew for 6 years and on the other of which timothy grew for the same length of time, were plowed, and were planted in one year to corn and in the next year to oats. The corn crop was considerably larger on the alfalfa land; the oats were equally good on the 2 plats. Analyses of the soils from the 2 plats showed that the alfalfa soil

contained not to exceed 0.01 per cent more nitrogen than did the timothy soil. When the soils were incubated, formation of nitrates proceeded more rapidly in the alfalfa soil than in the timothy soil.

"These data raise, but are not sufficiently exhaustive to answer, two questions: (1) Whether there was a greater accumulation of nitrogen in the alfalfa soil during the 6 years than there was in the timothy soil during the same period; (2) whether the greater productivity of the alfalfa soil was not due to the more ready availability of the nitrogen in the alfalfa soil rather than to its greater quantity.

"Plots of land that were to be sown to alfalfa were inoculated with (1) soil from an old alfalfa field, (2) a culture of *Bacillus radicola* in moist muck, (3) the same preparation air-dried, (4) a culture of the same bacillus on the seed. Yields of 3 crops were obtained from which it appears that moist muck is a suitable medium for the growth of *B. radicola* (the germ that forms nodules on the roots of alfalfa plants), and that this material may be air-dried and successfully used for the inoculation of soil on which alfalfa is to be planted."

[Wheat and rye in Turkestan], B. M. BENZIN (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.)*, 6 (1913), No. 7, pp. 457-495, pls. 6, figs. 6).—This gives descriptions and dimension data of spikes, spikelets, and kernels for each of 2 varieties of wheat and rye that are cultivated in Turkestan and which were found not to shatter grain readily when ripe.

A study of statistical methods with barley, W. O. WHITCOMB (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 2, pp. 83-101).—The material used in this study consisted of 2 varieties of barley, known as New Zealand and Berkeley. Each variety consisted of 30 pure lines of 10 plants each or 300 plants in all.

A comparison of the constants for the 5 characters, yield per culm, height per culm, number of kernels per culm, number of spikelets per culm, and weight per kernel, "when determined by using the average for the entire plant as one method and the main culm of the same plant as the other method, indicate the following: (a) The means and standard deviations are quite uniform and are larger in most cases when determined with the main culm; (b) the coefficients of variability are slightly larger when determined by the use of the whole plant; (c) the correlation coefficients are not uniformly different when determined by the 2 methods, and are of approximately equal value, with some exceptions, when determined by either method.

"The general conclusion based on this study is as follows: Within certain limits, the biometrical constants as determined by using the main culm of barley plants are of equal value and are comparable with those obtained by using the entire plant as the unit."

Data are presented in 30 tables.

Experiments with beans (Poroto mantecoso), F. ALVAREZ (*Bol. Min. Agr. [Buenos Aires]*, 15 (1913), No. 3, pp. 289-292).—This gives results of cultural tests, including cost of production, at Bella Vista. The yield was at the rate of 1,752 kg. per hectare (1,559 lbs. per acre).

Ear characters not correlated with yield in corn, A. G. MCCALL and C. WHEELER (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 2, pp. 117, 118).—The authors show by using data of complete records of ear-to-row test work furnished from the Ohio Experiment Station and a test field at Forest, Ohio, covering the years from 1905 to 1911 and including over 600 ears, "that so far as these tests are concerned neither length, weight, circumference, nor density of ear is correlated with yield."

Corn growing in Manitoba, W. C. MCKILICAN (*Canada Expt. Farms Bul.* 14, 2. ser. (1913), pp. 22, figs. 12).—This bulletin gives directions for the pro-

duction of corn in Manitoba and describes implements to be used, styles of silos, and silo filling.

Annual report of the Nebraska Corn Improvers' Association (*Ann. Rpt. Nebr. Corn Improvers' Assoc.*, 4 (1913), pp. 114, figs. 6).—This report contains among other data 15 papers on corn and wheat growing and related subjects, including some results given by W. M. Jardine of seed-bed preparation experiments conducted at the Kansas Experiment Station since 1907, from which "the main conclusion to be drawn is that large quantities of nitrates, or plant food as indicated by nitrates, are developed and stored in the soil as a result of early seed-bed preparation." Tabulated results for 1911-12 show that the wheat yields varied on the same scale as the nitrogen content of the soil to a depth of 3 ft., when determined in the spring and the fall of each year, for each of 10 methods of seed-bed preparation.

Report of variety tests of cotton for 1913, and a summary of results for the past eleven years, R. Y. WINTERS (*North Carolina Sta. Bul.* 226 (1914), pp. 15).—The results of tests at 3 locations showed that "at the experiment station farm the short staple varieties ranged in yield between 434.5 and 1,045 lbs. of seed cotton per acre. The 54 short staple varieties produced an average yield of 799 lbs. of seed cotton or 304 lbs. of lint and 495 lbs. of seed. The 15 long staple varieties ranged in yield between 479.5 and 927 lbs. of seed cotton, giving an average yield of 774 lbs. of seed cotton, or 264.5 lbs. of lint and 509 lbs. of seed."

"The 47 varieties of short staple cotton grown at the Edgecombe farm ranged in yield between 1,200 and 540 lbs. of seed cotton per acre. The varieties on this farm produced an average yield of 849 lbs. of seed cotton, or 313 lbs. of lint and 536 lbs. of seed per acre. The long staple varieties ranged in yield between 980 and 540 lbs. of seed cotton per acre and produced an average yield of 700 lbs. of seed cotton or 228 lbs. of lint and 472 lbs. of seed per acre."

At the Iredell farm, "ranging in yield from 300 to 1,560 lbs. of seed cotton per acre, the short staple varieties gave an average yield of 944 lbs. of seed cotton or 367 lbs. of lint and 577 lbs. of seed per acre. The above is a much broader range in yield than was secured at either of the other farms. Both the maximum and minimum yields exceeded the range of the other two. The long staple varieties ranged in yield between 350 and 960 lbs. of seed cotton per acre and produced an average yield of 768 lbs. of seed cotton or 263 lbs. of lint and 505 lbs. of seed."

Some of the best yielding varieties are noted to be Hawkins Extra Prolific, Shine Early Prolific, King Improved, and Cook Improved.

The Knapp method of growing cotton, W. B. MERCIER and H. E. SAVELY (*Garden City and New York, 1913*, pp. XV+208, pls. 33, figs. 4).—This book gives a history and description of the cotton plant, and treats of climate, soil culture, fertilizers, seed improvement, varieties, diseases and insect pests, harvesting, marketing, cost of production, equipment in teams and tools for cotton farms, cotton by-products, and soil improvement. It also discusses the outlook for the cotton industry and the supply and distribution of cotton.

Standard tests for hemp, G. E. ANDERSON (*Daily Cons. and Trade Rpts. [U. S.]*, 16 (1913), No. 280, p. 1111).—This notes a method of standardizing that is now being tested by the bureau of agriculture at Manila, in which the breaking strength of a meter length of fiber is divided by its weight in grams. It is hoped that the resulting gram-meter value will be an accurate index of the comparative strength and quality of the fiber.

Sisal hemp: Planting, manufacturing, and general management, D. J. STODDART (*Jour. Jamaica Agr. Soc.*, 17 (1913), Nos. 6, pp. 17-20; 7, pp. 14-18, pl. 1, fig. 1; 8, pp. 34, 35; 9, pp. 17-19; 10, pp. 12-14).—The hemp industry is

reviewed, and the cultivation, manufacture, and general management of hemp discussed with a view to Jamaican production. The topics covered are as follows: Description and varieties of sisal hemp plants; soil and its preparation; selection and method of cultivation; catch crops; maturity and harvesting; quality; machinery, drying stand, press, and buildings; artificial drying, baling, and bagasse; yields and values; and the fields as grazing pastures. Many of the data given are taken from Yucatan conditions.

Cultivation of main-crop potatoes (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 4, pp. 764-774).—This gives general directions for producing a potato crop in Ireland, and includes results of some tests by the department of agriculture in which potatoes were allowed to sprout before being planted. The average results obtained in every county in Ireland during the 10 years 1903-1912 showed that sprouted seed yielded 12 tons 5 cwt., and unsprouted seed 10 tons 6 cwt. per acre.

The advantages of storing potatoes during the winter in sprouting boxes are noted as follows: "(1) A substantial increase in yield; (2) planting may be deferred for a time in an unfavorable season without detriment to the crop; (3) several weeks' growth is secured in the boxes previous to planting; the first bud is preserved, which results in the crop making rapid growth when planted, enabling it to smother weeds; (4) the crop is usually ready for lifting several weeks before that from unsprouted seed; (5) seed potatoes can be safely and conveniently stored in boxes and easily examined for the removal of unsound tubers or for the detection of those of other varieties which may have been accidentally introduced."

Results are given of manurial experiments with potatoes conducted at 353 centers during the 11 years, 1901-1911.

Potato production from experience, G. M. TWITCHELL (*Ann. Rpt. N. J. Bd. Agr.*, 40 (1912), pp. 140-149).—This paper, which was delivered at the fortieth annual meeting of the New Jersey State Board of Agriculture, deals with the production of the potato crop as developed in Maine. The methods employed in establishing different types of potatoes are described. It is noted that by protecting the vines and increasing the leaf development a potato of increased starch content may be obtained, and that the use of Paris green injures the leaf surface and delays elaboration therein.

Some experiments on the growth of rice in water culture, V. E. VILLEGAS (*Philippine Agr. and Forester*, 2 (1912), No. 4-6, pp. 86-90).—The results given in this paper were obtained in a study of the inferior crop-producing power of cogon soils. Rice plants were grown in water cultures with and without an extract from cogon soils, in the presence of various nitrogen compounds, and in the presence of a soil extract obtained from under a clump of bamboo.

The results obtained showed that "rice grown in water culture containing substances extracted from cogon soil is generally retarded in its growth; where sodium nitrate is the predominating fertilizer stimulation of growth is observed. The extract from a soil growing bamboo retards the growth of rice in every case, though the effect observed is less in the case of the plant grown in a solution containing sodium nitrate as the sole nutrient salt. . . . It is evident that the removal of nitric acid from the solutions containing sodium nitrate will tend to develop an amount of alkali sufficient to neutralize more or less completely the acidity due to superphosphate. In fact the solutions containing predominating proportions of sodium nitrate were the only ones which were neutral at the end of the experiment. . . . We, therefore, conclude that cogon soil and soil growing bamboo contains a substance or substances injurious to the growth of rice in acid media; whether the toxic action would

be noticed if the plants were grown in neutral or slightly alkaline media remains for further investigation."

Tabulated data are given.

The influence of salts common in alkali soils upon the growth of the rice plant, K. MIYAKE (*Jour. Biol. Chem.*, 16 (1913), No. 2, pp. 235-263).—From the results of 2 experiments to determine the influence of single salts upon the growth of rice seedlings the author concludes that "the alkali salts under examination act as agents both toxic and stimulating upon the growth of rice seedlings, according to their concentrations. The toxic concentrations of magnesium sulphate and chlorid, calcium chlorid, sodium chlorid and carbonate are greater than 1/100-normal while sodium sulphate and bicarbonate are greater than fiftieth-normal. The highest stimulation is observed in the dilution of 1/500-normal for magnesium sulphate, 1/1,000- to 1/5,000-normal for magnesium chlorid, 1/1,000- to 1/5,000-normal for calcium chlorid, fiftieth-normal to 1/100-normal for sodium chlorid, 1/100- to 1/500-normal for sodium carbonate and bicarbonate."

In studying the antagonism between the toxic effects of 2 salts upon the growth of rice seedlings, the results of 10 experiments that included the use of MgSO_4 , CaCl_2 , Na_2SO_4 , MgCl_2 , and NaCl , showed that "the salts under examination, used separately, are very poisonous in tenth-normal concentration upon the growth of the rice plant, but when the 2 salts are mixed with each other in a suitable proportion, the toxic effect of each salt more or less completely disappears. This result is of great importance in alkali soil investigations. The antagonistic action of salts is due to that of the ions formed by the dissociation of the salt. In general, divalent cations are markedly antagonized by monovalent cations, but on the other hand, monovalent cations do not strongly antagonize divalent cations. Among the divalent cations, calcium shows a more marked antagonism than magnesium. The antagonism between Cl' and SO_4'' , though it is small in comparison with that between cations, is also present in no slight degree."

In 14 experiments as to the antagonistic action of sodium and potassium salts, which included NaNO_3 , KCl , KNO_3 , NaCl , K_2SO_4 , and Na_2SO_4 , the results showed that "sodium and potassium salts are antagonized by each other. The curve of antagonism between these salts shows 2 maxima and the location of these maxima is almost constant, occurring at the point of the proportion of 5:25. This coincides with the result which was observed by Osterhout on wheat seedlings. The antagonism between these salts is due to cations as well as anions. The antagonism between anions is small in comparison with that between cations."

In studying the antagonism between potassium and magnesium or calcium ions, 2 experiments in which KCl , MgCl_2 , and CaCl_2 were used showed that "potassium and magnesium or calcium salts are poisonous to the rice plant when used separately but when mixed together in suitable proportion the poisonous effect more or less completely disappears. The results coincide with those of Osterhout and form an important factor in the question of soil fertility."

As to the possibility of barium and strontium replacing the antagonistic action of calcium, 2 experiments in which MgCl_2 and NaCl were used as the toxic salts, showed that "the injurious effect of certain metallic ions upon the growth of rice seedlings may be perfectly counteracted only by the presence of calcium ions. Strontium ions can exert an influence only slightly retarding the toxicity of the metallic ions. Barium ion not only has no beneficial action but

a depressing effect is observed. Consequently, it is concluded that barium and strontium can not replace the antagonistic action of calcium."

Tabulated data of the results of these experiments are given in terms of length of leaf, length of root, and number of roots.

On the composition of rice of Siam, G. LIBERI (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 6 (1913), No. 2, pp. 225-246; *abs. in Ztschr. Gesam. Getreidew.*, 6 (1914), No. 3, p. 61).—Some rices of Siam are classified into 3 types, and data on the dimensions and weights of kernels of these types are given. The lengths ranged from 4.94 to 8.58, the widths from 1.97 to 3.19, and the thicknesses from 1.42 to 2.19 mm.

Chemical analytical data are given in tabular form for about 30 samples from these types and comparison is made with Italian rice.

On the influence of variety, preceding crop, fertilizer, and stand upon the yield of rye, GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 5 (1913), No. 5, pp. 360-402).—Tabulated data give results of tests of about 12 varieties covering the years 1909-1912.

The results of a previous treatment of the soil showed fallow and lupine as a green manure to be unprofitable, except that on sandy soil lupine could be plowed under with profit. Good yields were obtained on clover sod, but the rye was more frequently damaged by pests. Good results were obtained after barley and oats, after an application of commercial fertilizers, and after early potatoes. It is noted that the best results were obtained when the rotation was such that the same crop did not always precede the rye. The small demands of the young rye plant made a supply of nitrogen-furnishing fertilizer in the fall unnecessary, but a spring application of nitrate of soda proved remunerative. Seeding at the rate of 120 kg. per hectare (107 lbs. per acre) with drill rows 12 to 15 cm. (4.7 to 5.9 in.) apart gave good returns.

Soy beans in South Africa, E. W. THOMPSON (*Daily Cons. and Trade Rpts. [U. S.]*, 16 (1913), No. 273, p. 955).—This notes the trial of over 80 varieties of soy beans at the government experimental farms in South Africa, some yielding 2,000 lbs. of beans and from 12 to 13 tons of green fodder per acre. It is noted that altitude seems to affect the yield of oil, as beans grown at an altitude of 3,354 ft. contained 20.65 per cent, at 500 ft. 21.36 per cent, and at 49 ft. 22.19 per cent of oil.

A seven-year variety test with stock beets, 1904-1910, G. BÖHMER (*Arb. Deut. Landw. Gesell.*, No. 243 (1913), pp. VIII+357).—This report gives data on growth, total yield, yield of leaves, yield of dry matter in leaves and roots, and percentage of sugar in tests carried on throughout Germany under the direction of the German Agricultural Society.

Will annual comparison of the quality of sugar-beet seeds give desired results? J. URBAN (*Ztschr. Zuckerindus. Böhmen*, 37 (1913), No. 9, pp. 444-448).—From a 2-year test the author concludes that all beet seeds maintain their relative quality in different years, this depending upon the inherited tendency of the respective seed. In other words, a beet seed with the inherited tendency to produce beets high in sugar will show this property in different fields and in all seasons.

On the influence of flowers of sulphur on the growth of sugar beets, J. URBAN (*Ztschr. Zuckerindus. Böhmen*, 37 (1913), No. 9, pp. 441-444).—This article gives a review of investigations along this line. The results obtained by the author in applying flowers of sulphur at the rate of 200 kg. per hectare (178 lbs. per acre) immediately after planting sugar-beet seed showed a slightly increased total yield, but no differences were observed in the color of the leaves during growth, in the sugar content of the beets, or in the quality of the juice.

Seedling canes and manurial experiments, J. P. D'ALBUQUERQUE ET AL. (*Local Dept. Agr. Barbados, Seedling Canes and Manurial Expts., 1911-1913, pp. 77*).—In this report methods of hybridizing sugar-cane plants and of obtaining self-fertilized seeds are described. Tables give results of variety tests of new seedlings and ratoons, with a summary of results since 1909. In manurial experiments, the results obtained by the use of barnyard manure, sulphate of ammonia, nitrate of soda, dried blood, superphosphate, basic slag, sulphate of potash, nitrate of lime, and nitrolime as fertilizers for sugar cane are given in tabular form for 1911-1913, as well as the average results obtained on the manurial experiment plats at Dodds for 20 years, 1894-1913. In these experiments nitrogen was applied at the rate of 60 lbs., potash 60 lbs., and phosphate 80 lbs. per acre each year.

The results showed that "where 60 lbs. of nitrogen as sulphate of ammonia was applied, 15 lbs. in January and 45 lbs. in June, there has been only a small gain over the 'no-manure' plat of \$2.74 and a loss compared with the 'no-nitrogen' plat of 70 cts. per acre per annum. Where 80 lbs. of nitrogen as sulphate of ammonia was applied, there has been a gain of only \$3.10 over the 'no-manure' plat and a loss when compared with the 'no-nitrogen' plat of 34 cts. per acre per annum for that period.

"With regard to the phosphate series, it is sufficient to say that in all the plats to which phosphates have been applied during the 20 years there has been a loss as compared with the 'no-phosphate' plats, with the exception of the plat to which 100 lbs. of basic slag has been applied per acre. In this case there was a gain of \$18.84 over the 'no-manure' plat and \$1.96 over the 'no-phosphate' plat. In the case of the 'no-phosphate' plat the gain over the 'no-manure' plat was \$16.88. With regard to the plats to which superphosphates were applied, the loss on the average per acre per annum for the 20 years varied from \$14.13 to \$6.18. In the case where 80 lbs. of basic slag was applied, the loss on the average for the 20 years was \$1.78 when compared with the 'no-phosphate' plat.

"In the potash series of all the plats, with the exception of the one to which 60 lbs. of potash as sulphate of potash was applied all in January there was an increase varying in the case of the 'no-manure' plat from \$2.75 to \$9.94 and in the case of the 'no-potash' plat from 56 cts. to \$5.13 per annum. In the case of the plat to which potash at the rate of 60 lbs. per acre was applied there was a gain of only \$2.75 over the 'no-manure' plat and a loss of \$2.06 when compared with the 'no-potash' plat."

Studies on the tobacco crop of Connecticut, E. H. JENKINS (*Connecticut State Sta. Bul. 180 (1914), pp. 3-65, pl. 1, figs. 14*).—"This bulletin is in no way a guide to tobacco growing or a treatise on the whole subject but simply brings together in small compass the general results of such work as this station has done in the interest of tobacco growers and handlers," and covers a period of perhaps 20 years. It was necessitated because of the exhaustion of the station's previous bulletins and reports on the subject.

The topics handled in this bulletin include quantity of nitrogen and mineral elements in the tobacco crop (leaves, stalks, total); relation between composition of ash and the burning quality; proximate composition of the leaf before and after fermentation; grain of tobacco; area of leaf surface on an acre of tobacco; seed production of tobacco; fertilizer experiments, that include loss of weight in fermentation, weight of leaves, fire-holding capacity, percentage of wrappers, yield, loss in sorting, comparative value of leaf from several plats, and the comparisons of nitrate of soda, cotton-seed meal, castor pomace, linseed meal, fish scrap, stable manure, tobacco stems, various forms

of potash, and the use of large amounts of phosphates; shaded tobacco; curing with artificial heat; fermentation of tobacco in case; fermentation of tobacco in bulk; tobacco breeding; insects which injure tobacco; and fungus diseases.

A bibliography of publications relating to tobacco of wrapper leaf type grown in New England, containing 92 titles, is appended.

Studies upon influences affecting the protein content of wheat, G. W. SHAW (*Univ. Cal. Pubs. Agr. Sci.*, 1 (1913), No. 5, pp. 63-126).—In this publication data are given of the results obtained in studying the seasonal, varietal, and individual variations in the protein content of wheat.

These experiments cover a period from 1906 to 1912, inclusive, and have shown that "in general the physical appearance of durum and red wheats is a fair indication of their relative protein content; kernels having a distinctly horny or glutenous appearance being higher in protein than those of a more or less dull or starchy appearance. There is a wide seasonal fluctuation in protein content of wheat which may become so great as to overbalance almost entirely any hereditary tendency of starchy originals to produce the same characteristics in their progeny. The protein content of wheat in a locality is undoubtedly largely dependent upon the seasonal precipitation in such locality. The use of perfectly typical glutenous seed is invariably followed under California conditions by a lowering of the gluten content, as indicated both by the physical appearance of the grain and by its protein content. If the original carries a considerable percentage of starchy kernels the progeny usually shows an increase toward the typical character to a degree determined by the character of the season in the locality. This is especially so with reference to the precipitation, which in some instances may have such a strong influence as to cause a practically perfect grain to result from an original seed carrying 100 per cent of starchy kernels. [It is also noted that] the character of the seed used has quite a marked influence upon the progeny, and that the quality of the seed used, to some degree at least, determines the character of the resultant crop, for, as the originals decrease in both percentage of typical kernels and protein the progeny in each case decrease in the same order, although the effect of this is materially lessened and sometimes almost entirely overcome by the character of the season. . . .

"There are important seasonal, varietal, and individual variations in wheat plants with respect to protein content. The principal factor causing the most pronounced variation in the protein content of wheats is climate, particularly the moisture supply in the later growing period of the crop. The tendency of wheat kernels to change from a glutenous to a starchy condition is not a constant one, but is mainly dependent upon the individuality of the plant and upon seasonal influences, particularly moisture supply in the latter part of the growing period of the plants. In wheats 100 per cent of which are entirely starchy there may be a reversion to an entirely glutenous condition in a single season, or the reverse may occur, dependent upon the seasonal condition.

"Allowing the grain to stand on the straw in the field until fully ripe does not materially affect the protein content. The protein content of wheat is affected by the time of seeding, the product of late seeded grain having a higher percentage of protein than that of early seeded grain. The protein content of wheat is very largely influenced by the water content of the soil in the later period of its growth, and the effect of either irrigation or rainfall during this period is to lower its protein content. The percentage of sunshine which the grain receives during its period of growth has a somewhat direct bearing upon its protein content, but other seasonal conditions are more important. Regarding the growth through cooling the atmosphere has a tendency to increase the protein content. The quantity of available nitrogen in the soil either alone

or in the presence of other available plant foods, provided there be sufficient to supply normal growth, appear to have little, if any, influence upon the protein content. The low gluten content of wheats grown in California is not due to soil exhaustion, but rather to the following causes: (1) To climatic factors which allow a long growing period; (2) to relatively early seeding; (3) to the use of varieties inherently low in gluten; (4) to a lack of selecting highly glutenous seed."

On the germination of wheat treated with some fungicides and insecticides, G. PICCHIO (*Coltivatore*, 59 (1913), No. 32, pp. 435-439).—It is noted that seeds immersed for 5 minutes in copper sulphate solutions ranging from 0.5 to 1.5 per cent in strength were not injured in germination ability, but increasing the strength up to 4 per cent in 0.5 per cent degrees caused a decrease in germinative ability until it reached 10 per cent.

A 40 per cent solution of formalin had little influence on the germinative ability of the seed placed in it for an hour. Vapor of carbon bisulphid had no effect on the quality of the seed.

Caffaro paste, a proprietary fungicide consisting chiefly of copper sulphate, had a similar effect, but not so marked as the copper sulphate.

Methods of seed germination tests, H. PIEPER (*Fühling's Landw. Ztg.*, 62 (1913), No. 18, pp. 625-633).—In his endeavor to find a method that would give results in germination tests that would run parallel to field conditions, the author tested oats, wheat, white mustard, lupines, and sainfoin by methods in which the seeds were covered with 3 cm. of either quartz sand, heavy clay, brick dust, sandy loam, or humus soil. Tabulated results are given.

It is noted that the method that employed quartz sand gave the most satisfactory results, as by it not only the viability but also the vegetative strength of the seeds could be determined.

The influence of atmospheric moisture, temperature, and oxygen of the air on stored seeds, M. HEINRICH (*Landw. Vers. Stat.*, 81 (1913), No. 3-6, pp. 289-376, pls. 2).—In this experiment there were used *Agrostis alba*, *Avena elatior*, *A. sativa*, *Beta vulgaris*, *Carum carvi*, *Centaurea cyanus*, *Daucus carota*, *Hordeum vulgare*, *Linum usitatissimum*, *Sinapis alba*, *Lupinus angustifolius*, *L. luteus*, *Lolium perenne*, *Medicago lupulina*, *M. sativa*, *Ornithopus sativus*, *Phleum pratense*, *Pisum sativum*, *Secale cereale*, *Spergula arvensis*, *Triticum sativum*, *Trifolium hybridum*, *T. pratense*, and *T. repens*. In studying the factors that might influence the viability of stored seeds the author handled moist seeds placed in a ventilated moist atmosphere; moist seeds in a confined atmosphere; air-dried seeds in a ventilated room atmosphere; air-dried seeds in a dried ventilated atmosphere; and seeds in various degrees of temperature from 0° to 30° C., and for several weeks (in some cases 70 weeks) under the above-mentioned atmospheric conditions.

It was concluded from the results that seeds, although high in hygroscopic water content, will retain their viability for a longer period when fresh air is admitted to them in storage. With free access of air the viability of seeds is not prolonged by previous drying of the seeds. The viability of seeds may be greatly prolonged even in a high temperature (30°) when artificially dried—stored with air excluded. A low water content for seeds stored with air excluded is considered advisable. A low temperature (under 5°) without exception favored the viability of seeds stored for a long period even though they contained a large amount of hygroscopic moisture. The viability of old seeds succumbed to unfavorable conditions more readily than did that of fresh seeds.

Data are presented in numerous tables.

Weed exterminator (*Cal. Cult.*, 41 (1913), No. 22, p. 533).—This notes success in the use of carbon bisulphid to exterminate weeds by a method that

introduces the liquid into the soil to the depth of from 2 to 3 in. by the employment of a pointed rod. The killing of anise and morning glory is mentioned.

Polygonum (Fagopyrum) tataricum as a weed in buckwheat fields in Volhynia, K. KAMENSKY (*Trudy Bûro Prikl. Bot. (Bul. Angew. Bot.)*, 6 (1913), No. 7, pp. 496, 497).—The appearance of this weed, probably coming from Siberia, is noted.

Apparatus for taking soil samples, I. SCHEWELEW (*Trudy Bûro Prikl. Bot.* 6 (1913), No. 7, pp. 441-448, pl. 1).—This describes an apparatus for taking from definite strata of soil samples of a given depth and volume, in which the quantity of weed seeds may be determined.

HORTICULTURE.

Report of the horticulturist, J. E. HIGGINS (*Hawaii Sta. Rpt. 1913*, pp. 22-26, pls. 2).—The horticultural investigations during 1913 were continued along the lines previously noted (E. S. R., 29, p. 234).

The results of the papaya investigations up to June, 1913, are presented in the bulletin noted on page 841. Among the recent developments in the work with papayas is a disease which is quite new to the station. It appears to be characterized by a wilting of the leaves and a decay of the stem, causing the sudden and entire destruction of the tree. The disease is now being studied by Lyon and Larsen at the Hawaiian Sugar Planters' Station and every precaution is being taken to prevent its spread. In connection with the change in sex of a papaya tree, brought about at times apparently by cutting back the top of the tree as discussed in the bulletin mentioned, a number of young male trees of a lot in which the females had matured no fruit were subjected to the removal of the growing portion at the end of the stem. In several instances there appears to be a large increase in the number of hermaphrodite flowers in the inflorescence just below the wound, although many of the trees showed no change whatsoever. None became pistillate trees, and it can not be observed that the new branches bear any more hermaphrodite flowers than the original stem. A similar experiment was conducted with 15 male trees which were several years old. Seven of these were cut off about 18 in. above the soil and 8 were cut leaving a stem about 4½ ft. high. None of these have yet shown any pistillate or hermaphrodite flowers. The indications are that old trees should not be cut lower than 4 or 5 ft., since 4 of those cut low have failed to put out any shoots, whereas shoots have grown on all but one of the trees cut high.

Observations on 2 lots of pineapple seedlings, secured from a single fruit in each case, show a very wide variation, a range in vigor from very weak to very robust, in color of foliage from dark green to bronze, in habit from upright to procumbent, and from very spiny to those which are practically spineless. In order to determine whether differences in the shape of fruit among plants supposedly of the same variety are purely incidental to environmental conditions or whether they represent characters which may be transmitted by asexual propagation, plants bearing both square and tapering fruits were selected for preliminary experiments in 1910. Measurements of the fruits of the progeny of these plants gathered in 1912 indicate a probable transmission of form characters by asexual propagation. In continuation of this experiment individual plants of marked character are being selected as they are found and the fruit of the progeny from these plants is to be compared with the fruit from the parent plants.

Experiments to determine the best seasons and methods for the pruning of peach trees in the tropical climate of the lowlands in Hawaii have been con-

ducted for a number of years. The best results have been secured by practically an annual renewal of the top. This pruning is done in June very soon after the gathering of the fruit. Although the foliage is almost entirely removed the tree soon sends out many new branches which grow vigorously until winter, when they begin maturing fruit buds. All suckers that are not required to improve the shape of the tree are removed.

In connection with the top-working of seedling avocado trees the best results have been secured by cutting the trees back to stumps about 1½ or 2 ft. high and budding the vigorous shoots rather than by budding the side branches of the original trees. Brief notes are given on the general condition of the experimental orchards. The *Feijoa sellowiana*, received from southern California in 1908, has made a satisfactory growth and fruited during the year for the first time.

The breeding investigations with ornamental hibiscus plants were continued by V. S. Holt, the important features of the work having been published in bulletin form (E. S. R., 30, p. 445).

Fertilizer experiments with tomatoes. A. L. DACY (*West Virginia Sta. Bul.* 142 (1913), pp. 3-27, figs. 6).—This bulletin reports the results of cooperative fertilizer experiments with tomatoes grown for the cannery in Morgan County, W. Va., in 1909, 1910, and 1911.

The fertilizer element most deficient in the soils included in these experiments was phosphoric acid. The tests failed to show any material difference between bone meal, basic slag, and acid phosphate as carriers of phosphoric acid. Although the effect of nitrogen was less marked it gave better net returns when used in the form of nitrate of soda either alone or in combination than when applied in the form of dried blood or cotton-seed meal. A test was made of quicklime in 1911 applied at the rate of a ton to the acre, both alone and in combination with stable manure, with a detrimental effect on the yield of the tomatoes. On the other hand, the beneficial effect of the lime was quite marked on the clover and vetch sown in the tomatoes at the last cultivation. High-grade commercial fertilizers gave better average net results with one exception than the same amounts of low-grade fertilizers. Based on the results as a whole, the author recommends the application of 400 lbs. to the acre of a commercial fertilizer containing 3 per cent nitrogen, 8 per cent available phosphoric acid, and 10 per cent potash, together with the addition of humus or organic matter to the soils by the use of stable manure and various green manures.

Hardiness of fruit buds and flowers to frost. F. GARCIA and J. W. RIGNEY (*New Mexico Sta. Bul.* 89 (1914), pp. 52, figs. 9).—The authors here report a study of the relative hardiness to frost of fruit buds and flowers at different stages of growth. In the investigation, which was conducted in the station orchard during the 5 seasons, 1909 to 1913, special attention was given to peach buds, although some data were also secured with plums, apples, pears, and apricots. In addition to the results of the above investigation, phenological data are given showing the blooming and fruiting period of 2 varieties of apricots and 7 varieties of plums for 7 years and of 6 varieties of peaches for 15 years. A record is also given of killing temperatures during March and April for the years 1892 to 1913, inclusive.

The data recorded at the station, especially for peach buds, show that the degree of resistance to frost varies with different stages of growth and that the bloom is not the most tender stage of the growth, the newly set peach being more delicate than the newly opened blossom. The peach is least resistant when it is about the size of a pea, when the calyxes are falling off. A tempera-

ture of 26° F. lasting only a short time did little or no injury to the opening bud, newly opened blossom, or newly set fruit of peach, native plum, pear, and apple, while one-half a degree below this (25½°), although lasting only a few minutes, killed a large percentage of the opening buds, newly set blossoms, and young fruit of the peaches in a number of cases. In some cases, however, a temperature of 24° lasting only a short time left about 25 per cent of the blossoms and 9 per cent of the newly set fruits uninjured. The longer the time the killing temperature remains and the nearer it is to sunrise the greater the amount of damage that should be expected. In cases where the minimum temperature occurred at midnight or a little later and then gradually rose to the freezing point so that the frozen buds, blossoms, and fruits had time to thaw out slowly before sunrise the injury was insignificant. Apples and pears seemed to be more resistant than peaches and plums. European and native plums seemed to be slightly hardier than Japanese plums and apricots. Apricots were the least resistant of all the fruits included in the test.

The susceptibility of most varieties of apricots, plums, and peaches to frost injury emphasizes the importance of choosing late blooming varieties, provided they are at least fairly satisfactory in other respects. The comparative temperatures for March and April taken in the valley and on the mesa show that the minimum temperatures were considerably warmer at the latter location.

Experiments in the dusting and spraying of apples, F. M. BLODGETT (*New York Cornell Sta. Bul. 340 (1914), pp. 149-179, pl. 1, figs. 4*).—In the experiments here reported finely ground sulphur plus lead arsenate applied both in liquid and dry form were compared with lime-sulphur-lead arsenate solution in the control of apple scab and insect pests.

The first experiments were started in 1911 but neither scab nor insects were present in sufficient quantity to secure any definite results. It was found, however, that the sulphur mixtures adhered remarkably well to the foliage and fruit and there was no indication of foliage injury or dwarfing. In 1912 a mild attack of scab was controlled about equally well by the three different treatments used. Arsenate of lead was about equally effective when applied with the lime-sulphur solution and with a suspension of sulphur. It was considerably more effective in the dry mixture than in either of the liquid mixtures. The experiments were continued on a larger scale in 1913. The details are given as to quantities of material used, dates of application and conditions influencing the same, time required, comparative costs, results, and methods of recording data.

From the data thus far secured in the investigation the author concludes that the use of finely ground sulphur as a fungicide and a dust mixture has given sufficiently encouraging results to warrant further trials on a more extensive scale. The application of arsenate of lead in powdered form in the quantities applied is more effective against the common orchard insects that chew than is the same substance applied wet. The cost of material and application of the dust mixture used in 1913 was as great or greater than the application of a wet spray. The time required for dusting an orchard is much less than that required for spraying. The opinion is advanced that the orchardist with additional acreage coming into bearing will probably be warranted in awaiting the results of another year's experimentation before buying additional spraying equipment.

Plum culture and district lists of plums suitable for Canada with descriptions of varieties, W. T. MACOUN (*Canada Expt. Farms Bul. 43, rev. ed. (1913), pp. 72, figs. 10*).—The present edition of this bulletin (E. S. R., 15, p. 476) has been revised to include the information gained from recent experience in connection with plum growing at the Central Experimental Farm.

Grafting Vinifera vineyards, F. T. BIOLETTI (*California Sta. Circ. 115 (1914), pp. 8, figs. 2*).—In the present circular the author discusses the grafting of Vinifera varieties of grapes on other varieties of the same species in distinction to the grafting of Vinifera varieties on American or phylloxera resistant stocks. Consideration is given to the choice and conservation of the scions, season of grafting, preparation of stock and scions, necessary tools, method of operation, and after treatment of grafted vines.

[Banana investigations at the Hilo substation], F. A. CLOWES (*Hawaii Sta. Rpt. 1913, pp. 50, 51*).—At the beginning of the year the cooperative station at Hilo was taken over as a substation and all experimental work discontinued except the banana experiment. This experiment was planned to study the influence of planting bananas at various distances apart. The distances used were 8 by 8, 10 by 10, 12 by 12, and 15 by 15 ft. Data secured on the first crop show that the yield increases as the planting distance decreases. It has been suggested, however, that the results of future crops may alter the standing of the various plots.

Factors governing the successful shipment of oranges from Florida, A. V. STUBENRAUCH, H. J. RAMSEY, L. S. TENNY, ET AL. (*U. S. Dept. Agr. Bul. 63 (1914), pp. 50, pls. 15, figs. 26*).—This comprises a report on harvesting, handling, and shipping experiments started during the season of 1907 and continued on a commercial scale through 5 shipping years. The work which was planned along lines similar to those followed in the California investigations (*E. S. R., 20, p. 43*) included the determination of the character and type of handling employed in the various operations of preparing fruit for shipment and the discovery of the relationship between prevailing methods and the occurrence of decay. The object of the work was to suggest changes in the industry which should reduce the immense annual financial loss of the Florida growers by enabling them to market their fruit in sound condition. The methods of handling the orange crop previous to the investigation, as well as the improvements which have been made during the course of the investigation, are described. The results of the various experiments are reported in detail and recommendations are made relative to handling the crop in order to secure the minimum of mechanical injuries.

The experiments during the past 7 years have proved conclusively, as in the California investigations, that the condition of the fruit after arrival at market depends largely upon the character of the work done in the grove and the packing house, that it is possible so to conduct the operations of picking, packing, and shipping as to inflict a minimum of mechanical injuries, and that uninjured Florida oranges can be placed on the market in practically sound condition. Even in seasons of very high decay practically all loss from blue mold decay such as has occurred in the past can be eliminated. In addition to the losses from blue mold, however, there has been considerable deterioration of Florida citrus fruits after arrival in market due to the attacks of the stem-end decay fungus. Unlike blue mold this fungus does not apparently depend upon injuries or breaks in the skin through which to gain entrance to the tissues of the fruit. An investigation during the season of 1910-11 in cooperation with the Florida Experiment Station proved conclusively that the stem-end rot disease can not be controlled by means of careful handling. The results of this investigation have been previously noted (*E. S. R., 26, p. 449*).

The papaya in Hawaii, J. E. HIGGINS and V. S. HOLT (*Hawaii Sta. Bul. 32 (1914), pp. 44, pls. 10*).—This bulletin comprises as a whole a progress report on the station's papaya cultural and breeding investigations (*E. S. R., 29, p. 234*) including a review of related literature of the subject.

In part 1, under the general heading of culture and uses, consideration is given to the natural requirements of papayas, propagation, transplanting large trees, irrigation, fertilizers, pruning in relation to change of sex, thinning the fruits, artificial feeding, renewing the plantings, the fruit crop, varieties, the papaya as a food (including recipes), medicinal and other uses, and papain, collecting the juice and preparing crude papain. Part 2 of the bulletin comprises a progress report on the work thus far accomplished in the attempt to secure improved strains of fruit by breeding. The subject matter is discussed under the following general headings: Botanical names, common names, botanical relationships, descriptions of forms of papaya, summary of forms, significance of the forms, change of sex, origin of different forms, origin of the dioecious *Carica papaya*, breeding with the dioecious forms, breeding the hermaphrodite forms, hermaphroditism in *Lychnis dioica*, breeding within the andromonoecious forms, crossing the different forms, parthenocarp, parthenogenesis, hybridization of *Carica*, an attempt to breed a hermaphrodite papaya, and ideals in breeding the papaya. A brief note on insect pests by D. T. Fullaway is also included.

The authors here recognize 13 forms and combinations in which the papaya occurs, with reference chiefly to the distribution of sexes and the shape of the fruit. Some of these forms are not constant, whereas others are distinct and have a practical bearing upon the subject of breeding. Of these latter the most important are the male and female of the dioecious papaya together with 2 andromonoecious forms and 2 hermaphrodite forms. With reference to inconstant forms the most primary change of sex which takes place is to be observed in the appearance of hermaphrodite flowers on trees that have previously produced only staminate inflorescence. This fruiting of the male papaya takes place most freely in cool climates outside the Tropics or at high altitudes. Aside from the influence of climate on change in sex there are many references in the popular literature of the papaya to the acquiring of fruit-bearing habits by the male tree due supposedly to some injury such as removal of the terminal bud or the breaking of the roots in transplanting old male trees. Iorns reported a case of this kind in which female flowers appeared on male trees as a result of the removal of the terminal bud. He concluded, however, that other conditions than the loss of the terminal bud must be present and suggested that the trees may pass through cycles of development (E. S. R., 20, p. 444). In another authenticated instance reported by J. T. Gulick female flowers with resulting fruit developed on a male tree which had been beheaded. Since methods such as these do not bring about similar results unfailingly, the authors conclude that certain unknown conditions are present, and suggest that the phenomenon may be due to bud variation. No record has been found which would indicate that the strictly female or pistillate tree has ever changed its sex. Some of these changes in sex when they have been brought about tend to reproduce themselves in the offspring of such plants.

A study of the difficulties which are met with in using the dioecious type for breeding purposes has led the authors to work principally with the hermaphrodite forms. The results of this work thus far show that it is possible by using a hermaphrodite parent to do away with the very large proportion of male trees which usually result from dioecious seed. Seed of one hermaphrodite tree found in a Honolulu papaya orchard and producing fruit of excellent flavor was grown to the second generation. Of 343 F_2 trees old enough to exhibit sex characters 94 per cent were fruit bearing. Although it is considered probable that varied forms of flowers and fruits will appear it is hoped that it will be possible to develop a pure strain of uniform shape.

To test the possibilities of pollination among the various flowers 17 different combinations of pollen and stigma have been tried. The results which are here presented in tabular form show comparatively few of these to have been wholly unsuccessful. It is observed from the data secured that certain individuals and stocks exhibit peculiarities of their own in relation to pollination. Hence, although it appears evident that any of the forms may be crossed, the results presented here are offered merely as cumulative data.

Certain trees have been found to be capable of parthenocarpic development of fruit but no cases of parthenogenesis have been recorded. The authors here outline some of the ideals which the papaya breeder should have in mind in the search for Mendelian characters which may be combined.

Top-working seedling pecan trees, W. N. HUTT (*North Carolina Sta. Bul. 224* (1914), pp. 3-23, figs. 17).—After persistent trials of all the known methods of budding and grafting through the varying conditions of 4 successive seasons the author here recommends the use of patch budding for top-working both young and old seedling pecan trees. This method of budding has given the highest percentage of successful unions year after year. The operation is here described in detail and fully illustrated.

FORESTRY.

Trees and how they grow, G. C. NUTTALL (*London, New York, Toronto, and Melbourne, 1913*, pp. XI+184, pls. 82).—In this popular work the author describes a number of our best known north temperate climate trees, tells how each one grows, and points out various interesting aspects of the trees at different seasons of the year.

Balsam fir, R. ZON (*U. S. Dept. Agr. Bul. 55* (1914), pp. 68, pls. 2, figs. 8).—This bulletin embraces the results of a 2 seasons' study of the balsam fir throughout the whole of the tree's commercial range. Consideration is given to the distribution of the balsam fir; the forest types in which it occurs; the present stand and cut; its economic importance, especially in relation to the paper pulp industry; methods and cost of lumbering; life history of the tree; characteristics of the wood; rate of growth and yield; and proper methods of management. A brief bibliography is appended.

The investigation shows that balsam fir is found in commercial quantities in the northeastern border States from Maine to Minnesota.

Tests of Rocky Mountain woods for telephone poles, N. DEW. BETTS and A. L. HEIM (*U. S. Dept. Agr. Bul. 67* (1914), pp. 28, figs. 8).—The purpose of the tests, here reported in detail, was to compare the strength of poles of western red cedar, the present standard telephone pole, and of lodgepole pine and Engelmann spruce, and also to determine the value for pole timber of fire-killed pine and spruce in the central Rocky Mountain region. The tests were conducted by the Forest Service of this Department in cooperation with the University of Colorado.

Air-seasoned lodgepole pine poles cut from live timber in Montana were fully equal in strength to the cedar poles tested. Pine and spruce poles cut from a fire-killed area in Colorado were inferior to cedar poles in maximum load developed, but the 3 woods were practically the same for stresses up to the elastic limit. The fire-killed pine after standing 10 years did not show deterioration to any appreciable extent when compared with seasoned lodgepole pine cut from representative live trees in Wyoming and Colorado. The ratio between the strength of the poles and the strength of the clear material cut from them is not constant for the different kinds of wood. The values were

highest for the cedar and lowest for the spruce, the pine representing an average for the 3 species.

Tyloses: Their occurrence and practical significance in some American woods, ELOISE GERRY (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 6, pp. 445-470, pls. 8).—The author briefly discusses the causes leading to the formation of tyloses and their function in the living plant, and reports a study of the occurrence and significance of tyloses in wood from trees of commercial size grown in the United States, 139 species having been examined. A bibliography of cited literature is included.

Tyloses were found in the sapwood of all the species where their presence was established in the heartwood. Well-developed tyloses were found in the outermost rings near the bark in 30 species of hardwoods. True tyloses were found to occur in the wood tracheids in certain pines, principally in the white pine group. Epithelial cells were found sometimes to effect a partial or even a complete tylose-like closing of the resin canals in *Pinus*, *Larix*, *Picea*, and *Pseudotsuga*. Tyloses are said to act like a natural filler in hardwoods, and woods where they occur abundantly are as a rule very durable. They reduce the penetrance of woods because they are impermeable to air, water, and creosote, thus decreasing, for instance, the tendency for woods to become water-logged. The closing of the vessels of hardwood by tyloses does not prevent the penetrance of preservatives, such as creosote, into the other wood elements.

Tyloses: A study of their occurrence and practical significance in some American woods, ELOISE GERRY (*Abs. in Science*, n. ser., 39 (1914), No. 998, p. 262).—The more important results secured in the investigations noted above are here summarized.

The selection system in forest economy, A. KUBELKA (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 11, pp. 1688-1695).—A discussion of the advantages and disadvantages of the selection forest as compared with even-aged stands grown under open conditions.

The present conditions of forestry in Italy, L. PICCIOLI (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 11, pp. 1682-1688).—The author here briefly reviews the evolution of forest laws in Italy in order to give an idea of the present forest conditions and the difficulties which are encountered in framing a single code of forest legislation without prejudice to the interests and customs of the population.

A bibliography of recent literature on the subject is appended.

Progress report of forest administration in Baluchistan for 1912-13, MULRAJ (*Rpt. Forest Admin. Baluchistan*, 1912-13, pp. 3+28).—A progress report of the administration of the state forests in Baluchistan, including a financial statement for the year ended June 30, 1913. The important data relative to forest areas, forest surveys, working plans, revenues and expenditures, etc., are appended in tabular form.

The lumber industry.—I, Standing timber (*U. S. Dept. Com. and Labor, Rpt. Comr. Corporations on Lumber Indus.*, pt. 1 (1913), pp. XXIII+301, pls. 2).—This comprises the first part of a statistical survey of the lumber industry of the United States which was undertaken by the Bureau of Corporations of the Department of Commerce and Labor in response to certain resolutions of Congress which called, in substance, for information on the causes of the high prices of lumber and whether or not these high prices have resulted from any contract, agreement, or combination in restraint of commerce. The present part discusses the importance of the lumber industry, the scope of the report and special principles involved, methods followed in the investigation, and the investigation area. The succeeding chapters deal with the supply of stand-

ing timber in the United States, concentration of timber ownership, acreage of timber holdings, value of standing timber, and the public land policy as a primary cause of concentration of timber ownership.

The foremost facts shown are the concentration of a dominating control of our standing timber in a comparatively few enormous holdings, steadily tending toward a central control of the lumber industry; vast speculative purchase and holding of timber land far in advance of any use thereof; and an enormous increase in the value of this diminishing natural resource, with great profits to its owners.

The lumber industry (*U. S. Senate, 61. Cong., 3. Sess., Doc. 818 (1911), pp. 38, pl. 1*).—A summary of the above report.

Forest products (*Bur. of the Census [U. S.], Forest Products, 1913, Nos. 1, pp. 10, fig. 1; 2, pp. 45; 3, pp. 10; 4, pp. 4; 5, pp. 8; 6, pp. 12; 7, pp. 6; 8, pp. 8; 9, pp. 8*).—A series of pamphlets compiled by the Bureau of the Census in cooperation with the Forest Service of this Department, and consisting of a statistical review for 1911 of the production, consumption, imports, and exports of the following forest products, arranged in order to correspond to the pamphlet numbers above: Pulpwood; lumber, lath, and shingles; slack cooperage stock; excelsior; veneers; tight cooperage stock; wood for distillation; cross-ties, including preservative treatments; and poles, including preservative treatments.

DISEASES OF PLANTS.

Proceedings under the destructive insects and pests act, 1877 and 1907, and the board of agriculture act, 1889, A. G. L. ROGERS (*Bd. Agr. and Fisheries [London], Ann. Rpt. Hort. Branch, 1912-13, pp. 57, maps 8*).—Accounts are given of the occurrence, distribution, methods of control, etc., of the gooseberry mildew (*Spharotheca mors-uvæ*), the wart disease of potatoes (*Synchytrium endobioticum*), tomato and cucumber canker (*Mycosphaerella citrullina*), the larch sawfly (*Lygæonematus erichsonii*), vine louse (*Phylloxera vastatrix*), and Mediterranean fruit fly (*Ceratitis capitata*), pests that are scheduled under the destructive insect and pest acts, and on the silver leaf disease and some other minor pests which are not scheduled.

Annual report on mycology, E. J. BUTLER (*Ann. Rpt. Bd. Sci. Advice India, 1911-12, pp. 124-127*).—The work carried on is briefly discussed and includes investigations of some sugar cane diseases, the occurrence of *Rhizoctonia* on cotton, peanuts, jute, cowpeas, potatoes, etc., and a disease of taro caused by *Phytophthora colocasiæ*. In addition brief accounts are given of studies on the grapevine mildew caused by *Oidium tuckeri*, the methods of control of the pink disease of Hevea caused by *Corticium salmonicolor*, and a rust of castor beans due to *Melampsorella ricini*.

Report on mycology, E. J. BUTLER (*Ann. Rpt. Bd. Sci. Advice India, 1912-13, pp. 116-122*).—An account is given of the chief diseases of plants investigated during the year. These include studies on the ufra disease caused by nematodes, the smut due to *Tilletia horrida*, false smut caused by *Ustilaginoidea virens*, and a disease due to *Sclerotium oryzae*. The rice diseases have been noted at length elsewhere (*E. S. R.*, 30, p. 244).

In addition to the above, notes are given on root rot of various crops due to a species of *Rhizoctonia*, sugar cane diseases, wheat rust in which it is stated that *Puccinia trititica* and *P. graminis* are the most important species of rust in India, an anthracnose of sisal hemp due to *Colletotrichum agaves*, cereal downy mildews in which it is demonstrated that in India these diseases are due to a species of *Sclerospora*, bud rot of palms, some tea diseases, etc.

The control of damping-off disease in plant beds, J. JOHNSON (*Wisconsin Sta. Research Bul. 31* (1914), pp. 29-61, pls. 2, figs. 7).—An investigation is reported on the cause of damping-off of seedlings in plant beds and methods for the control of this trouble. In Wisconsin the disease is commonly caused by *Pythium debaryanum* and a species of *Rhizoctonia*. These fungi attack a large variety of plants and their development is favored by excessive moisture and high temperatures.

For preventing attacks of these fungi a number of chemical agents have been tested, among them formalin, copper sulphate, ammonium copper carbonate, copper acetate, copper nitrate, Bordeaux mixture, lime sulphur mixture, potassium sulphid, sulphuric acid, potassium permanganate, mercuric chlorid, potassium nitrate, and iron sulphate. Of the chemicals tested a solution of formalin 1 part to 50 of water at the rate of 2 qt. per square foot of soil will prevent damping-off under the most favorable conditions for fungus growth. It was also found somewhat beneficial in stimulating plant growth and killing weed seeds. Sterilization of soil by heat gave the most satisfactory results and the inverted pan method is recommended where facilities are at hand for its application. Attention is called to the secondary effects of soil sterilization in that weed seeds and insect pests are killed and the vigor of plant growth is stimulated.

As a cultural means of control of this disease, growers are recommended to avoid infected, poorly drained soils and thick sowing of seed. Where the disease is present the covers of the plant beds should be removed so as to reduce the temperature and moisture of the soil as well as that of the air in contact with the plants. A list of the literature cited is appended.

The relation of *Fusarium nivale* to *Nectria graminicola*, J. WEESE (*Ztschr. Gärungsphysiol.*, 2 (1913), No. 4, pp. 290-302).—Reporting a study of *F. nivale*, claimed by Ihssen (E. S. R., 23, p. 545) to be a stage of *N. graminicola*, the author states that these two fungi are not identical.

A study of some imperfect fungi isolated from wheat, oat, and barley plants, E. C. JOHNSON (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 6, pp. 475-490, pls. 2).—Attention is called to the fact that many imperfect fungi are parasitic on cereals wherever climatic conditions favor their development. A study was made of some of these fungi occurring on wheat, oats, and barley, and pure cultures were obtained of *Fusarium culmorum*, *Helminthosporium gramineum*, *Cladosporium gramineum*, and a species of *Alternaria*, and after profuse sporulation had been induced tests were made of their pathogenicity on the leaves, seeds, and seedlings of wheat, oats, barley, and rye.

Inoculation experiments in the greenhouse showed that certain species greatly reduced the germination and development of the plants. The root development of wheat plants attacked by *Helminthosporium* was stunted and the roots were markedly inferior to those developed on plants grown from clean seed. An experiment on soil infection showed that this was a possible means by which the *Helminthosporium* attacked the cereal, and the experiment indicated that the soil remained infected for at least two months, during which the experiment was in progress. Field experiments with these fungi substantiated the results obtained in the greenhouse, although the reduction in germination and injury to seedlings was somewhat less in the field experiments.

The author concludes from his experiments that *H. gramineum* and *F. culmorum* were parasitic, while *C. gramineum* and the undetermined species of *Alternaria* were not parasitic under the conditions of his investigations.

A brief bibliography is given.

The culture of cereal rusts in the greenhouse, F. D. FROMME (*Bul. Torrey Bot. Club*, 40 (1913), No. 9, pp. 501-521).—The author describes experiments by

which he was able to propagate the uredo stage of rusts in the greenhouse for several months. The species experimented upon were *Puccinia dispersa* and *P. coronifera*. These were carried through 37 generations of the uredo stage.

P. coronifera was found not to self-propagate to any extent, even when abundant host material was present and a constant humidity of 93 per cent was maintained. This high humidity was found essential in securing inoculations with uredospores of this species. The total exclusion of light either early or late in the incubation period of the fungus affected its development and resulted in an almost complete cessation of growth. The uredospores of *P. coronifera*, when stored at room temperatures, were found to lose their capacity for germination gradually, only 0.2 per cent germinating after a storage of 84 days.

A bibliography is appended.

Report of 1908-1912 studies on celery diseases in Hamburg lowlands, H. KLEBAHN (*Jahrb. Hamburg. Wiss. Anst.*, 30 (1912), *Beiheft 3*, pp. 1-57, pls. 2).—These investigations are said to have confirmed previous conclusions (E. S. R., 22, p. 746) regarding the agency of *Septoria apii* and *Phoma apicola* in producing respectively leaf spot and scab of celery. It is claimed to have been shown that seed often carry fruiting bodies of *S. apii*, also that the spores live through the winter on plant rubbish in large numbers. Scab is also said to be transmitted through the seed and plant waste, but very slightly by means of air currents.

Directions are given for the manufacture and employment of a number of fungicides recommended.

Diseases of the potato tuber and the selection of sound seed, R. W. JACK (*Rhodesia Agr. Jour.*, 11 (1914), No. 3, pp. 399-407, pls. 5).—The author briefly describes scab due to *Oospora scabies*, corky scab caused by *Spongospora scabies*, Rhizoctonia stem rot, dry or white rot due to *Fusarium solani*, bacteriosis or wet rot due to *Bacillus solanacearum*, nematode disease, etc.

For the prevention of these different diseases the choice of seed from uninfected regions is advised, and where suspected seed is obtained treating the tubers with formalin or corrosive sublimate solutions is recommended.

The perennial mycelium of *Phytophthora infestans*, I. E. MELHUS (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 18-19, pp. 482-488, figs. 2).—It is claimed to have been shown in the experiments here described that the mycelium of *P. infestans* may spread from the tuber into the young shoots, developing in the portions above ground and producing aerial spores which may become the source of secondary infections. A detailed account of the author's experiments is to be published in a later contribution.

Spraying of potato crop, C. McDONALD and R. MCKENZIE (*North of Scot. Col. Agr. Expt. Leaflet 29* (1913), pp. 118-122).—It is claimed, as the result of an analysis of the figures obtained in 53 trials, that there was an average increase on sprayed plats of 4,000 lbs. of sound tubers per acre, the quality also showing improvement. A few cases in which there was little or no improvement are explained by heavy rainfall just after spraying or by too great delay in its employment.

A disease of spinach, P. PASSY (*Jour. Soc. Nat. Hort. France*, 4. ser., 15 (1914), Feb., pp. 106, 107).—A brief account is given of a disease of spinach which is thought to be of bacterial origin. The infected plants lose their green color, turning yellow. Later the leaves become partially destroyed, the disease beginning in the petiole, which is destroyed, and eventually the plant dies. Preliminary investigations have shown that the trouble is confined to the aerial parts of the plants, the roots retaining their normal appearance.

A leaf curl of tobacco in Kamerun, K. LUDWIGS (*Ber. Deut. Bot. Gesell.*, 31 (1913), No. 9, pp. 536-543, figs. 4).—A leaf curl of tobacco is discussed which is ascribed to abnormal nutrition resulting from a disproportionate water supply. A similar abnormality is said to have been noted in other plants and it is thought likely that still others may be affected in the same way.

Finger-and-toe experiments, A. MANSON (*North of Scot. Col. Agr. Expt. Leaflet 24* (1913), pp. 24, 25).—This report states that where infection was abundant and in the soil only, early preparation of the land for turnips reduced the disease considerably, but that where the infected manure was applied to the surface in autumn, little difference was noted. Aeration and insolation are thought to be important factors in destruction of the infection.

Finger-and-toe, A. PARDY (*North of Scot. Col. Agr. Expt. Leaflet 25* (1913), p. 52).—The results of the experiments were obscured by a rotting of the turnips due to frosts, but the cheap fungicides and other materials applied to the manure exposed in the drill appeared to have some good results where used in liquid form. Chlorid of lime showed good results. Limewater showed better results than lime, and copper sulphate and soluble alkalis showed some slight influence.

Manuring and variety tests with turnips for finger-and-toe disease, A. T. FOWLIE (*North of Scot. Col. Agr. Expt. Leaflet 28* (1913), p. 102).—Plats dressed with freshly slaked shell lime showed much less finger-and-toe disease than those dressed with an equal quantity of ground lime or limestone, which still showed improvement over the untreated portion. Two varieties of turnip seed were tested for alleged immunity. Both withstood disease better than local seed and gave a satisfactory increase of crops.

Scab disease of apples, E. WALLACE (*New York Cornell Sta. Bul. 335* (1913), pp. 541-624, pls. 11, figs. 4).—The author describes the disease of apples due to *Fusicladium dendriticum*, the conidial stage of *Venturia inaequalis*, describing symptoms, importance, etiology, and methods of control.

This disease, which is generally known as scab in the United States, is also called black spot, scurf, and sometimes rust where it occurs on the leaves and fruit. The life history of the fungus is discussed at length and the author claims that early infection is chiefly, if not entirely, from ascospores. The period of incubation may vary from 8 to 15 days, although as the first crop of ascospores is not all matured and discharged at the same time the source of infection is practically constant. The earliest infections usually occur on the lower side of the leaves. Some differences in varietal susceptibility have been reported by the author in common with other investigators, and it is found that certain varieties may be resistant one year and very susceptible the next under conditions which are apparently as favorable one year as the other.

For the control of the disease various fungicides have been tested and both lime sulphur and Bordeaux mixture have been found efficient if properly applied. Lime sulphur is preferred as usually there is less russetting of the fruit than is the case where Bordeaux mixture is used. The effect of spraying trees while dormant has been tested and two seasons' work did not materially reduce the amount of scab. Spraying fallen leaves is apparently without benefit, as the spores are protected from the fungicide until after their discharge takes place. The effect of continued spraying year after year is believed to be cumulative, although the author does not report any experiments of his own to confirm this.

The bulletin concludes with an extensive bibliography.

The yellow leaf disease of cherry and plum in nursery stock, V. B. STEWART (*New York Cornell Sta. Circ. 21* (1914), pp. 10, figs. 9).—A brief description

is given of the leaf blight, commonly known also as yellow leaf or shot-hole, of plums and cherries, due to *Cylindrosporium padi*, which is said to attack not only the sweet cherry, but some of the wild cherries, and is quite common on sour cherries and certain varieties of plums.

Symptoms of the disease and methods of control are discussed at length. It is said that both Bordeaux mixture and lime-sulphur solution may be used for the control of this disease. A 5:5:50 solution of Bordeaux mixture or a lime-sulphur solution at a strength of 1 gal. to 50 gal. of water are recommended. The addition of granulated iron sulphate to the solution is said to prevent the danger from burning and also to increase the sticking qualities of the solution.

Diseases of young grapevines, L. RAVAZ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 1, pp. 3-6, pl. 1, figs. 4).—This is mainly a brief review of recent work and conclusions by several investigators named, most of whose contributions have already been noted.

Recent observations on *Stilbum flavidum* (*Agron. Colon.*, 1 (1913), No. 6, pp. 179-181).—This is a brief note regarding the report by Maublanc and Rangel, previously noted (*E. S. R.*, 30, p. 652).

[Notes on tea diseases], A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, No. 3 (1912), pp. 79, 80).—The author reports that the principal tea blights noted on a recent tour in northern Terai were red rust and a root disease caused by *Ustilina zonata* (a formula for treatment for the latter being given). Blister blight on two kinds of jungle plants has been shown to be capable of infecting tea, but attempts to inoculate the former hosts with spores from the latter have not been successful. Investigations regarding the possibility and conditions of spore survival during winter are in progress.

Leaf roll and starch storing in *Syringa*, R. LAUBERT (*Gartenflora*, 63 (1914), No. 1, pp. 9-11, fig. 1).—The author describes an abnormality of lilac leaves characterized by paleness of the outer portions, rolling and stiffening in mid-summer or earlier, followed by their death and fall in July or later. No pathogenic organisms were found, but tests showed abundant presence of starch in the discolored portions. The trouble is thought to be of physiological character, possibly due to unfavorable culture methods.

Immunity in plants, H. ORDNUNG (*Mitt. Deut. Dendrol. Gesell.*, No. 22 (1913), pp. 172-176).—The author discusses the occurrence of the oak mildew (*Microsphaera quercina*), the white pine blight (*Cronartium ribicola*), and other parasitic diseases of forest trees, calling attention to their destructive occurrence in some localities upon certain species or varieties, while other host plants are more or less immune to attack. In the case of some of the species he thinks the extension of industrial works has, through their smoke, weakened the trees and made them more subject to fungus attacks, which are said to be always most severe on the first appearance of a fungus in epidemic form. Later, by acquired immunity through the elimination of the weaker individuals, a considerable degree of resistance is produced.

An investigation on the methods of propagation of mistletoe and the injury caused by that parasite (*Bul. Mens. Off. Renseig. Agr. [Paris]*, 13 (1914), No. 2, pp. 132-181).—The results are given of an inquiry made of the directors of agriculture and foresters of different departments and conservation areas of France regarding the host plants, distribution, effect, etc., of mistletoe.

According to the reports, it is found very rarely on the oak, somewhat more frequently on maple, beech, alder, etc., and quite commonly on some of the species of *Populus* and on certain fruit trees. The nature of the soil in which the host is growing does not appear to influence its occurrence and it is seldom

found growing at elevations of more than 1,000 meters. Nearly all responses attribute its distribution mainly to birds, and particularly to thrushes and other migratory birds.

Nodules on Hevea rubber trees, R. D. ANSTEAD (*Planters' Chron.*, 9 (1914), No. 2, pp. 14, 15).—This paper contains information compiled from several sources.

It is said that no connection has been proved between the bark nodules described as noted on Hevea and attacks by any insect or fungus. The nodules are known to occur before tapping, but they are seen much more frequently afterwards. Overtapping, high elevation, dry weather, and in general, conditions that tend to reduce the vitality of the trees are mentioned as factors in the production of burs and nodules.

Disease of Para rubber trees, W. R. RUTTER (*Ann. Rpt. Bot., Forestry and Sci. Dept. Uganda*, 1913, pp. 5, 6).—A description is given of an attack of *Fomes semitostus* on Para rubber trees in the garden connected with this institution. The disease is thought to be introduced in the rubber plantations through the ground not being properly cleared of decaying timber and stumps previous to the planting out of the rubber seedlings.

Dry rot investigations, A. MÖLLER (*Hauschwammforschungen*, VII. Jena, 1913, pp. V+20).—This contribution by the editor of the series reported by Falck et al. (E. S. R., 28, pp. 750, 751) gives a systematic summary of the commission's findings since the beginning of its work in 1905, regarding the biological, practical, and legal aspects of timber dry rot associated with *Merulius lacrymans* and related fungi, with references to publications previously issued.

Dry rot in factory timbers, F. J. HOXIE (*Boston*, 1913, pp. 34, figs. 19).—In a report to the inspection department of the Associated Factory and Mutual Fire Insurance Companies the author gives the results of an investigation of 15 or 20 cases involving a study of several thousand beams affected by dry rot. It is claimed that the present supply of timber available for mill construction is subject to danger, the neglect of which is resulting in serious consequences. The author's study was made of hard pine timber such as is used for heavy mill frames.

The principal injury is caused by the fungi *Merulius lacrymans* and *Coniophora cerebella*, although another species was sometimes met with. The author found that the percentage of resin in hard pine can be taken as an index of its power of resistance to dry rot. Hard pine timber 12 in. square or larger is practically unobtainable with sufficient natural resistance to withstand action of fungi in moist atmospheres. The nonresinous, sappy hard pine is said to be not safe for use for the important parts of a building without antiseptic treatment. Holes through columns, narrow spaces between beams, and hollows between floors and roofs are of no value in preventing dry rot and serve to spread it rapidly to all susceptible material. Heating a new building to 115° F. for 24 hours or more several times has been found valuable in preventing serious loss from dry rot.

Of the various antiseptic treatments in practical use, corrosive sublimate appears to be the best adapted to the treatment of mill timber. Some modification of the present process is believed necessary when deeper penetration of the antiseptic is required.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Catalogue of the mammals of western Europe (Europe exclusive of Russia) in the collection of the British Museum, G. S. MILLER (*London*, 1912, pp. XV+1019, figs. 213; rev. in *Science*, n. ser., 38 (1913), No. 970, pp. 159-

162).—This catalogue lists and describes 314 recognized forms representing 69 genera.

The review is by J. A. Allen.

The fauna of the German colonies, G. AULMANN (*Fauna Deut. Kolon. [Berlin Zool. Mus.]*, 5. ser., No. 5 (1913), pp. IV+126, figs. 99).—This fifth part of the work, previously noted (E. S. R., 29, p. 653), deals with the enemies of rubber plants.

Relative efficiency of rat traps.—Type of trap which has proved most effective in Manila, V. G. HEISER (*Pub. Health Rpts. [U. S.]*, 29 (1914), No. 6, pp. 341, 342).—It appears that the spring trap is far more economical as well as more effective than the cage trap.

The birds of North and Middle America, R. RIDGWAY (*U. S. Nat. Mus. Bul.* 50, pt. 6 (1914), pp. XX+882, pls. 36).—This sixth part of the work previously noted (E. S. R., 26, p. 346) deals with the families Picidae, Capitonidae, Ramphastidae, Bucconidae, Galbulidae, Alcedinidae, Todidae, Momotidae, Caprimulgidae, Nyctibiidae, Tytonidae, and Bubonidae, which include the woodpeckers, kingfishers, barn owls, eared owls, etc.

The bobolink (*Dolichonyx oryzivorus*) as a conveyer of Mollusca, C. T. RAMSDEN (*Auk*, 31 (1914), No. 2, p. 250).—Live mollusks (*Succinea riisei*), known from the islands of St. Croix and Porto Rico but not from Cuba, are reported to have been found among the feathers of several male bobolinks captured at Guantanamo, Cuba, on April 18, 1913.

An unusual observation on the crow (*Corvus brachyrhynchos*) at Lubec, Maine, C. H. CLARK (*Auk*, 31 (1914), No. 2, pp. 248, 249).—The author reports having observed a flock of crows capture and feed upon the body of what appeared to be a sanderling.

A new bacillus isolated during an epidemic among frogs, F. VENULET and L. PADLEWSKI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 71 (1913), No. 5-7, pp. 343-348, pl. 1; abs. in *Jour. Roy. Micros. Soc. [London]*, No. 1 (1914), p. 68).—An epizootic disease among frogs associated with edema, more particularly of the extremities, and great weakness is said to have been due to *Bacillus septicaemiae ranarum* n. sp. "The bacillus is a slender Gram-negative rod, possessing one flagellum, motile, and not forming spores. It is pathogenic for certain fishes, crabs, guinea pigs, rabbits, and pigeons. The organism forms a toxin to which guinea pigs and rabbits are susceptible."

Handbook of entomology, edited by C. SCHRÖDER (*Handbuch der Entomologie*. Jena, 1912, vol. 1, No. 1, pp. IV+160; 1913, vol. 1, Nos. 2, pp. 161-320; 3, pp. 321-480; 4, pp. 481-528, figs. 390; vol. 3, pp. 1-112, figs. 43; rev. in *Science*, n. ser., 37 (1913), No. 962, pp. 872, 873).—Volume 1, by P. Deegener et al., of this 3-volume work deals with the anatomy, histology and morphology of the larvæ and imagoes; embryology, general morphology, metamorphosis, etc. Chapters 1 to 6 of volume 3 by A. Handlirsch take up the history of entomology, entomological literature and its use, entomological technique, classification, nomenclature, and terminology of the parts of the exoskeleton of systematic importance. Bibliographies are appended to each chapter.

Treatise on forest entomology, A. BARBEY (*Traité d'Entomologie Forestière et l'Usage des Forestiers des Reboiseurs et des Propriétaires de Bois*. Paris and Nancy, 1913, pp. XIV+624, pls. 8, figs. 367; *Ann. Sci. Agron.*, 3. ser., 6 (1911), II, Nos. 5, pp. 348-373; 6, pp. 419-439; 4. ser., 1 (1912), I, Nos. 3, pp. 181-225; 4, pp. 241-282; 6, pp. 426-459; II, Nos. 3, pp. 167-199; 4, pp. 271-298; 5, pp. 348-379; 6, pp. 420-445; 2 (1913), I, Nos. 5, pp. 379-412; II, Nos. 3, pp. 293-361; 4, pp. 420-501; 5, pp. 583-668; 6, pp. 750-797, pls. 8, figs. 367).—The first part of this work (pp. 1-24) consists largely of a discussion of insects, their

structure, classification, etc. The main part of the work gives a brief discussion of insects of general interest to the forester and then deals with the subject under the headings of 19 of the more important trees attacked. Colored plates are appended.

A text-book of medical entomology, W. S. PATTON and F. W. CRAGG (*London, Madras, and Calcutta, 1913, pp. XXXIV+768, pls. 89, figs. 3*).—The successive chapters of this work, several of which are divided into sections, take up the subject as follows: (1) Introduction (pp. 1-7); (2) anatomy and physiology of blood-sucking Diptera, general structure, and the internal structures (pp. 8-150); (3) the Orthorhapha-Nematocera and Orthorhapha-Brachycera (pp. 151-308); (4) the Cyclorrhapha and Pupipara (pp. 309-433); (5) the Siphonaptera or fleas (pp. 434-477); (6) the Rhynchota or bugs (pp. 478-526); (7) the Anoplura or lice (pp. 527-564); (8) the Ixodidae or ticks (pp. 565-680); (9) mites (pp. 681-697); (10) the Pentastomida and Eucepoda (pp. 698-710); (11) laboratory technique (pp. 711-728); and (12) the relation of Arthropoda to their parasites (pp. 729-745). A complete subject index is included.

A contribution to exact biology, A. HANDLIRSCH (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 122 (1913), I, No. 3, pp. 361-481, figs. 5*).—The first part of this paper (pp. 362-396) deals with the relation of the metamorphosis of insects to their distribution in climatic zones.

Entomological research committee report for 1912-13 (*Colon. Rpts., Ann. [Gt. Brit.], No. 781 (1914), pp. 10*).—A report of the work of the committee since October, 1912.

[Entomological investigations in Ontario], L. CAESAR and A. W. BAKER (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 38 (1912), pp. 26-28*).—Black-leaf 40 when combined with lime-sulphur and applied to apple trees just before the buds burst or shortly after the aphid eggs hatched gave excellent results, almost every aphid being destroyed. It was found that spraying with lime-sulphur mixture on April 25, nearly 2 weeks before the buds burst, and in May as they were bursting both gave almost perfect results.

Injuries in a Spy orchard were found to have been caused by the young nymphs of the hemipterous species *Lygidea mendax*, *Paracalacoris colon*, and *Neurocolpus nubilus*. The damage is done by the nymphs which puncture and suck the fruit, leaves, and twigs after the blossoms fall.

A mixture consisting of 4 lbs. of arsenate of lead to 40 gal. of water sweetened with 1 gal. or more of molasses was the most effective in combating the rose chafer of any yet tested. The closely allied species *Rhagoletis fausta* was found to be associated in some districts with the cherry fruit fly in damaging Montmorency cherries.

Tests of arsenite of zinc on the codling moth and potato beetle at Guelph gave as good results as arsenate of lead.

Report of the entomologist, D. T. FULLAWAY (*Hawaii Sta. Rpt. 1913, pp. 18-21*).—This brief report of the work of the year includes a list of 60 insect forms, representing 9 orders, collected during the course of a trip to Laysan Island in December-January; a list of insects injurious to vegetables in Hawaii; and a brief discussion of the present status of work with the Mediterranean fruit fly.

The insects and other galls of plants in Europe and the Mediterranean Basin, C. HOUARD (*Les Zoocécidies des Plantes d'Europe et du Bassin de la Méditerranée. Paris, 1913, vol. 3, pp. 1249-1560, pls. 4, figs. 202*).—This supplement to the work previously noted (*E. S. R., 22, p. 657*) deals with the subject under the headings of the various plant families concerned. Bibliographical, zoological, and botanical indexes are included.

Carnivorous insects in the region of Paris, CHRÉTIEN (*Hyg. Viande et Lait*, 8 (1914), No. 3, pp. 113-129, figs. 10).—The subject is taken up under the headings of Diptera, Lepidoptera, Hymenoptera, Orthoptera, and Coleoptera.

Administrative report of the government entomologist, April 24, 1912, to March 31, 1913, T. B. FLETCHER (*Rpt. Dept. Agr. Madras, 1912-13*, pp. 36-41).—This report deals with the occurrence of the more important insect enemies and control measures.

Insect enemies of plants in Surinam, J. KUYPER (*Dept. Landb. Suriname Bul.* 31 (1913), pp. 17-22, pls. 2).—These miscellaneous notes relate to injury to Hevea plants by *Dilophonota ello* and *Saissetia nigra*; to sugar cane by *Castnia leucis*; to cacao by *Rutela lineola*; and to the orange by *Mytilaspis citricola*.

The occurrence of animal enemies and of diseases of the sugar beet in 1912, A. STIFT (*Bl. Zuckerrübenbau*, 20 (1913), Nos. 1, pp. 7-10; 3, pp. 39-43; 4, pp. 55-58).—This is a discussion of the occurrence of the more important pests during the year, with references to the literature.

Insect pests of truck and garden crops, 1913, A. L. LOVETT (*Oreg. Agr. Col. Bul.* 91 (1913), pp. 39, figs. 13).—This is a popular account of the more important insect enemies of truck and garden crops in Oregon, with recommendations as to treatment and a discussion of insecticides.

Apple insects, W. J. SCHOENE and B. B. FULTON (*New York State Sta. Circ.* 25 (1913), pp. 11, pls. 4, figs. 11).—Brief popular accounts are given of the more important apple insects occurring in New York State with the treatment therefor.

Injurious citrus insects, A. J. COOK (In *California Citrus Culture. Sacramento: State Com. Hort.*, 1913, pp. 51-82, figs. 30).—This is a summarized account of the insect enemies of citrus and means for their control.

Termites or white ants (*Agr. News [Barbados]*, 13 (1914), Nos. 309, p. 74; 310, p. 90).—Studies of material submitted to the Imperial Bureau of Entomology for examination show 10 species representing 5 genera to occur in the Lesser Antilles and 1 additional species in Porto Rico. Two of the species occurring in the Lesser Antilles were found to be new to science.

A Venezuelan reduviid (*Rhodnius prolixus*) in which *Trypanosoma cruzi* develops, E. BRUMPT and GONZALEZ-LUGO (*Bul. Soc. Path. Exot.*, 6 (1913), No. 6, pp. 382, 383).—The authors report that dejections of this hemipteran contain trypanosomes and are infective for more than 2 months after it has sucked the blood of an infected animal.

Reduviidæ of North America capable of transmitting *Trypanosoma cruzi*, E. BRUMPT (*Bul. Soc. Path. Exot.*, 7 (1914), No. 2, pp. 132, 133).—*T. cruzi* which occurs in nature in *Connorrhinus megistus*, *C. infestans*, and *C. sordidus* has been found by the author, who studied a virus received from Bahia, also to develop in several species of *Cimex* (*C. lectularius*, *C. rotundatus*, and *C. boueti*) and in *Ornithodoros moubata*. Eggs from a species of *Connorrhinus* received from Texas developed nymphs which were fed upon infected mice. The dejections were found to contain pure cultures of *T. cruzi* and the author thinks it probable that the infection is durable.

The tea seed bug, C. B. ANTRAM (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, No. 4 (1911), pp. 14-18, pls. 2).—The two pentatomids *Pæcilicoris latus* and *P. hardwickii* have been well known on tea estates in northeastern India but until quite recently have not been considered of economic importance. It has recently been found that the juice of both ripe and unripe tea seed is the natural food of these insects, and the evidence at hand indicates that they are responsible for a certain amount of fungus-diseased tea seed.

The wheat bug (*Ælia germari cognata*) (*Bul. Agr. Algerie et Tunisie*, 19 (1913), No. 12, pp. 257, 258, fig. 1).—This plant bug periodically invades the cereal fields of the high plateaus and is the source of considerable injury.

Contribution to the study of *Helopeltis*, C. BERNARD (*Dept. Landb. Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee*, No. 17 (1912), pp. 1-19, pl. 1).—This is a report of studies of *Helopeltis* in the Dutch East Indies.

The avocado membracid (*Hoplophora monogramma*), J. R. INDA (*Bol. Dir. Gen. Agr. [Mexico], Rev. Agr.*, 2 (1912), No. 2, pp. 142-145, pl. 1).—This membracid is a source of considerable injury through its attack on the leaves and branches of the avocado.

On the Chermesidæ of Switzerland, N. A. CHOLODKOVSKY (*Russ. Ent. Obozr.*, 12 (1912), No. 3, pp. 597-600; *Schweiz. Ztschr. Forstw.*, 64 (1913), No. 4, pp. 114-117).—A brief discussion of the occurrence and injury of the more important species found in Switzerland, based on personal studies by the author.

The mealy bugs of California, E. O. ESSIG (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 3, pp. 97-143, figs. 46).—In this paper the author presents a popular account of the mealy bugs. The subject is taken up under the headings of classification, general character, life history, economic and noneconomic species, host plants, descriptions of species including food plants and distribution, natural enemies, and artificial means of control.

Woolly aphids of the elm, EDITH M. PATCH (*Maine Sta. Bul.* 220 (1913), pp. 259-298, pls. 6, figs. 19).—The author states that it has been the intention in the preparation of this bulletin and Bulletin 217, previously noted (*E. S. R.*, 30, p. 548) to bring together all available information on this group of elm aphids, as a progress report.

The species briefly noted are the woolly aphid of elm bark (*Schizoneura rileyi*), a new elm gall for America (*S. lanuginosa* ?) recently collected in Connecticut, elm rosette or leaf cluster aphid (*S. lanigera* [*americana* in part of authors]), southern elm leaf curl (*S. lanigera* [*americana* in part of authors]), northern curl of American elm (*S. americana* in part of authors), and elm currant aphid of Europe (*S. ulmi* [*fodtensis*]). The notes on each species are accompanied by a bibliography.

The third part of the Food Plant Catalogue of the Aphidæ of the World (*E. S. R.*, 28, p. 60; 29, p. 654) follows (pp. 274-298).

Silkworm experiments, C. W. WOODWORTH (*California Sta. Circ.* 116 (1914), pp. 4).—This circular announces that the station is prepared to distribute silkworm eggs free of charge to anyone willing to cooperate in the effort to make silk culture profitable in California. While the growing of silk has in the past been unprofitable in this State there is said to be a possibility that the cost of production can be diminished in one way and another sufficiently to place the industry on a sound financial basis. Brief directions are given for the feeding and care of the worms.

The brown-tail moth (*Euproctis chrysorrhœa*), W. E. BRITTON (*Connecticut State Sta. Bul.* 182 (1914), pp. 3-26, figs. 16).—This is a general account of the brown-tail moth, its occurrence in Connecticut, remedial measures, etc.

The sugar-cane borer (*Diatræa saccharalis obliterallis*), A. H. ROSENFELD and T. C. BARBER (*Rev. Indus. y Agr. Tucumán*, 4 (1914), No. 6-8, pp. 233-366, pl. 1, figs. 25).—This work deals with the history and occurrence in Argentina of *D. saccharalis*, its life history, habits, natural enemies, and means of control. A bibliography of 10 pages is appended.

Hypsopygia costalis, injurious to lucern hay in the Romagna, Italy, D. SEROZZI (*Italia Agr.*, No. 18 (1913), pp. 444-451, pl. 1; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 12, pp. 1928, 1929).—This moth, which has been recognized since 1902 as a source of

injury to sulla hay in central Italy, has now begun to attack alfalfa hay in the Romagna, the larvæ destroying the leaves almost completely, leaving only the stems with a few petioles. In an average attack, or when the hay does not consist entirely of alfalfa, the loss is at least 20 per cent and it may reach 50 or 60 per cent. Carbon bisulphid has not been found effective for disinfecting the hay stacks, and the author recommends that when a stack is attacked it be fed as quickly as possible to prevent the development of the larvæ.

The *Chelonia* caterpillars, F. PICARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 9, pp. 261-266, pl. 1).—This paper relates largely to *Arctia* or *Chelonia caca*, a widespread pest, and its natural enemies.

Tapinostola muscosa, a noctuid moth injurious to cereals in Hungary, J. JABLONOWSKY (*Kösztelek [Budapest]*, 23 (1913), No. 99, pp. 3335-3337, figs. 3; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intcl. and Plant Diseases*, 5 (1914), No. 2, p. 285).—This cutworm was the source of damage to oats and barley on an estate in Hungary, some 40 acres being so badly infested that the crops had to be plowed under.

The flight of the house fly, E. HINDLE (*Proc. Cambridge Phil. Soc.*, 17 (1914), No. 4, pp. 310-313).—"House flies tend to travel either against or across the wind. This direction may be directly determined by the action of the wind, or indirectly, owing to the flies being attracted by any odors it may convey from a source of food. The chief conditions favoring the dispersal of flies are fine weather and a warm temperature; the nature of the locality is another considerable factor, as in towns flies do not travel as far as in open country, this being probably due to the food and shelter afforded by the houses.

"Under experimental conditions, the height at which the flies are liberated and also the time of day influence the dispersal of the insects. When set free in the afternoon they do not scatter so well as when liberated in the morning. From our experiments the usual maximum flight in thickly housed localities seems to be about a quarter of a mile, but in one case a single fly was recovered at a distance of 770 yds. It should be noted, however, that part of this distance was across open fen land."

The cambium miner in river birch, C. T. GREENE (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 6, pp. 471-474, pls. 2).—The dipterous species *Agromyza pruinosa*, unlike most other members of the Agromyzidæ, has the habit of mining in the cambium of the living tree, the mine leaving a scar known as a "pithray fleck." Investigations in Europe have shown that at least the pith-ray fleck in birch is caused by *A. carbonaria*, which is closely related to the species here considered. The work of *A. pruinosa* is said to be very common in river birch in the District of Columbia, every tree that was examined in one locality in 1912 containing new work. The work of the species found in wild cherry is said to be identical with that in red maple and black birch. The trees attacked are apparently healthy and infested ones can not be detected by their outward appearance, the removal of the bark and exposure of the cambium being the only way in which this can be done. Pith-ray flecks were also found in red oak (*Quercus rubra*) at Charter Oak, Pa., and in mountain holly (*Ilex monticola*) at Endeavor, Pa., but the insect or insects concerned have not been determined.

Brief descriptive accounts are given of the morphology and biology of the several stages of this miner. The egg is apparently deposited in the fork of two branches. A hymenopterous parasite, *Symphya agromyzæ* n. sp., a brief description of which by S. A. Rohwer is given in a footnote, issued from a pupa case of *A. pruinosa*. The egg of this parasite is said to be deposited within the egg of the host. The apparently normal dipterous larva mines down the tree

trunk and enters the ground; the pupa is perfectly formed, outwardly exhibiting no signs of parasitism, but about the time the host should emerge the parasite issues instead.

Some common lady beetles of Connecticut, W. E. BRITTON (*Connecticut State Sta. Bul.* 181 (1914), pp. 3-24, figs. 24).—This bulletin gives brief descriptive accounts of the lady beetles of greatest economic importance and their occurrence in Connecticut, and calls attention to their beneficial habits. There are said to be over 30 species that occur in the State. The accounts of many of the species are accompanied by illustrations.

Scydmaenus chevalieri n. sp. in Senegal, A. VUILLET (*Bul. Soc. Ent. France*, No. 9 (1913), p. 238; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, p. 1304).—This beetle is said to live on the fruit of the peanut (*Arachis hypogaea*).

A new endemic fern weevil of the genus *Heteramphus*, O. H. SWEZEY (*Proc. Hawaii. Ent. Soc.*, 2 (1913), No. 5, pp. 210, 211).—A new species of weevil is said to mine the fronds of several species of *Elaphoglossum*. A small chalcidid (*Omphale metallicus*) parasitizes the weevil pupæ.

Miscellaneous contributions to the knowledge of the weevils of the families *Attelabidæ* and *Brachyrhinidæ*, W. D. PIERCE (*Proc. U. S. Nat. Mus.*, 45 (1913), pp. 365-426).—This paper includes fixations of the types of all of the North American genera in these 2 groups and descriptions of 4 new genera, 2 new subgenera, 24 new species, and 9 new varieties.

The biology of the large brown pine beetle (*Hylobius abietis*) and remedial measures, GROHMANN (*Tharand. Forstl. Jahrb.*, 64 (1913), No. 4, pp. 325-361, figs. 3).—A detailed report of studies.

A contribution to the comparative physiology of digestion, H. PETERSEN (*Pflüger's Arch. Physiol.* 145 (1912), No. 1, pp. 121-151, pls. 2, fig. 1).—This article relates to digestion in the honeybee.

Apiculture in British Columbia, L. HARRIS and F. D. TODD (*Brit. Columbia Dept. Agr. Bul.* 42 (1913), pp. 63, figs. 23).—This bulletin deals with modern methods of bee keeping as adapted to British Columbia, and also embodies reports of the foul brood inspectors for 1911.

A new braconid parasite of *Sinoxylon sexdentatum* in grapevine shoots, F. PICARD (*Bul. Soc. Ent. France*, No. 16 (1913), pp. 399-402, fig. 1; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 2, p. 280).—A new braconid parasite (*Monolexis lavagnei* n. sp.) has been found to attack the bostrychid beetle *S. sexdentatum*, which commonly destroys grapevine shoots in southern France. In addition it has been found to parasitize two oak pests, *Scobicia pustulata* and *Xyloniites praeustus*, and Corsican pine enemies of the genera *Pityogenes* and *Pityophthorus*.

On a new species of *Mymaridæ* from Trinidad, C. O. WATERHOUSE (*Bul. Ent. Research*, 4 (1913), No. 1, pp. 87, 88, fig. 1).—A description is given of *Anagrus flaveolus* n. sp., which was reared from the eggs of the corn leaf hopper, *Peregrinus (Delphax) maidis*, in Trinidad. It is closely allied to *A. frequens*, originally described from Hawaii, and *A. columbi*, from Columbus, Ohio.

Description of a new species of *Corymbites* from the Sonoran zone of Washington State, J. A. HYSLOP (*Proc. Biol. Soc. Wash.*, 27 (1914), pp. 69, 70).—It is stated that *Corymbites noxius* n. sp. was reared from larvæ which were attacking wheat in the Big Bend country of the State of Washington.

Studies on the habits and development of a hymenopterous parasite, *Spalangia muscidarum*, C. H. RICHARDSON (*Jour. Morph.*, 24 (1913), No. 4, pp. 513-557, figs. 17; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. B, No. 2, pp. 23, 24).—This article deals with the systematic relationships of the genus *Spalangia*, the geographical distribution of the genus, hosts of *Spalangia*, normal

activities of the imago, food, habits, hypermetamorphosis in the Hymenoptera, the larval types, hypermetamorphosis in *S. muscidarum*, musculature, effect of the parasite upon the host, economic importance, etc. A bibliography of 46 titles is appended.

The genus *Spalangia*, of which a list of 28 recognized species is given, is widely distributed throughout North America and Europe and a number of species have also been recorded from Central and South America and the Hawaiian Islands. Although a decided preference is shown for Diptera as hosts, their parasitism is not restricted to this order and some attack Lepidoptera, while others are myrmecophilous.

Notes on Tetrastichini, N. B. KURDJUMOV (*Russ. Ent. Obozr.*, 13 (1913), No. 2, pp. 243-256, figs. 8).—This paper includes a synoptic table of the genera of Tetrastichini and tables for the separation of species of the genera *Geniocerus*, *Aprostocetus*, and *Tetrastichus*, with descriptions of 1 species belonging to the first mentioned genus and 2 species belonging to the last mentioned as new to science.

Protozoan parasites of Ichneumonidæ, C. MORLEY (*Entomologist*, 46 (1913), No. 600, p. 169).—The ichneumonid *Stenichneumon trilineatus*, which commonly parasitizes the gooseberry moth (*Abraxas grossulariata*), has been found by Fantham and Porter (*E. S. R.*, 30, p. 459) to be attacked by 2 protozoa. One of these is a species of the genus *Nosema* to which the name *Nosema ichneumonis* has been given; the other is a flagellate belonging to the genus *Herpetomonas* to which the name *Herpetomonas ichneumonis* has been applied.

The cherry fruit sawfly (*Hoplocampa cookei*), E. O. ESSIG (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 1, pp. 31-35, figs. 3).—"The cherry fruit sawfly is a native of California and other Pacific coast States and has been known since 1883 in the Suisun Valley, Cal. Considerable damage to young cherries has been done in various sections by the larvæ of this insect and occasionally, at least, control measures may be necessary. The presence of the insect may be told by the small round holes bored in the young green cherries, many of which soon drop to the ground. . . . Control measures have not been thoroughly perfected but two applications of arsenate of lead at the rate of 4 to 5 lbs. to 100 gal. of water, the first application to be made shortly before the blossoms open and the second about 10 days later, have proved effective. Fall plowing is also recommended to kill the larvæ and pupæ in the soil while a distillate oil emulsion and nicotin spray is recommended to kill adults at time of egg laying.

"The insect has been reported as occurring in the Suisun Valley, Eldorado and Nevada counties, Cal., and at Medford, Oreg., where it is confined to a very small area. The orchard fruits attacked are cherry (sweet and sour), prune, plum, peach, and apricot (the peach and apricot only occasionally)."

The occurrence of a tenthredinid (*Emphytus braccatus*) on the oak, J. C. NIELSEN (*Naturw. Ztschr. Forst u. Landw.*, 11 (1913), No. 12, pp. 554-557, figs. 3).—A brief note on the occurrence of this sawfly in Denmark.

Ticks in the West Indies (*Agr. News [Barbados]*, 13 (1914), No. 310, p. 90).—This is supplementary to the paper previously noted (*E. S. R.*, 27, p. 460).

The Brazilian species of the subfamily Heterakinæ, L. TRAVASSOS (*Mem. Inst. Oswaldo Cruz*, 5 (1913), No. 3, pp. 271-318, pls. 5).—Of the 50 species of nematodes of the genus *Heterakis* listed 16 are said to occur in Brazil, 2 being described as new to science.

FOODS—HUMAN NUTRITION.

Some results of a study of the factors of bread making, ANNA W. WILLIAMS (*Jour. Home Econ.*, 6 (1914), No. 1, pp. 21-28).—The author has included

in her study the following factors: The liquid used, the yeast, the fermentation, the manipulation of the dough, and the temperature. Some of her conclusions follow:

"The amount of flour required to give a dough of a certain consistency varies according to the kind of liquid used. Water produces a finer textured, sweeter flavored, but more inelastic bread than do any of the liquids ordinarily used for mixing. But such bread dries out more rapidly than any other.

"When potato water is used the lightness and sponginess of the bread is increased to a marked degree. The use of milk, either sweet or sour, or of potato water heightens the color of the crust. The use of potato water also increases slightly the rapidity of fermentation, but the use of buttermilk increases it somewhat more. Potato water increases greatly the keeping qualities of the bread in which it is used. Milk, either sweet or sour, also increases such qualities, but to a less extent. . . .

"The volume of a loaf is influenced by the power of the yeast to act in the oven, this power being proportional to the amount of yeast. Length of time of rising in the oven is increased by an increase in amount of yeast. When a good quality of yeast is used an increase up to 2 cakes per loaf is to be recommended for shortening the time and producing better bread, although it can not be recommended from an economic standpoint. . . . Yeast, if introduced in small quantity into a sponge, will multiply until it assumes a maximum concentration, and if introduced in large quantity will cause a greater immediate production of gas, but will not give a more vigorous sponge ultimately.

"A small amount of yeast will give the same results as a larger amount if allowed a sufficient length of time in a sponge. . . .

"Fineness of texture was much more dependent upon the degree of rising allowed in the pan than upon the extent of the previous risings. Even doughs which were permitted to rise and fall in the bowl stage gave fine grain on proper treatment in the pan. . . . Underlightness in the first risings showed in the finished product in lack of mellowness and elasticity. Bread seemed better for having been allowed to reach its maximum expansion once during the process.

"Bread allowed to finish its rising in the oven is undoubtedly better in texture, although more care is required in baking to give a well shaped loaf. . . .

"A kneading stroke which was long and firm and even, covering all portions of the dough alike, and a rather quick stroke so that the dough was kept constantly in motion seemed to be the most effective sort.

"The method of molding into the loaf had also considerable effect on texture; the loaves that were not kneaded, but were molded lightly at this point, showed more plainly the effects of handling in the early stages. In all cases the formation of a compact dough, on molding into the loaf, resulted in a loaf of small volume and dull crust, but of fine and even texture; the loaf was, however, too compact, and lacked lightness and silkiness. The loaves which were lightly molded, without kneading, were superior in all points except in fineness and evenness of texture. . . .

"Overheating of the dough during rising results in a loaf of small volume, coarse texture, dark crumb, and dull, unattractive crust.

"Chilling of bread tends to lessen its volume, and to produce compactness, coarseness, and toughness of crumb.

"There is very little difference in the short process breads raised at the temperatures of 26 and 40° C. Such difference is not enough to justify the additional length of time demanded by the lower temperature.

"Doughs which are thoroughly warmed during mixing and kneading are not easily chilled afterward. . . .

"The baking temperature must be regulated according to the degree of lightness of the dough. Too hot an oven causes an underraised dough to crack after crusting over, thus producing holes in the crumb, while too cool an oven allows fairly well risen dough to become overlight. . . .

"The retention of moisture during baking, as in a covered pan or, under some conditions, in a fireless cooker increases the volume and weight of the loaf, but makes the crumb overmoist. The volume is increased because the presence of steam prevents the crusting over of the loaf, thus allowing it to rise more."

Some consideration was given to the effect of bacteria in bread making. As a result of the investigation as a whole, the author states that a score card was proposed for use in judging bread.

The staling of bread, E. VERSCHAFFELT (*Pharm. Weekbl.*, 49 (1912), Nos. 27, pp. 631-635; 52, pp. 1218, 1219; *abs. in Ztschr. Untersuch. Nahr. u. Genussmitl.*, 26 (1913), No. 11, p. 668).—The results of microscopical studies are reported.

According to the author's conclusion, stale bread shows a small but marked difference from fresh bread. When examined in water the starch grains appear distinct from the gluten. In stale bread small fissures filled with air are noticeable around the starch grains, which are absent in fresh bread. This indicates that the starch grains have shrunk in volume, a conclusion in accord with the observed fact that the absorption coefficient of the starch of stale bread is lowered.

"Lime bread" (*Pure Products*, 10 (1914), No. 1, pp. 29, 30).—The material here described was prepared under the direction of Prof. Emmerich, of Munich, and contained 20 cc. of a 10 per cent solution of crystallized calcium chlorid to every 2 lbs. of flour, the purpose of the addition being to supply the lime, which, according to Emmerich and Loew, is not supplied in sufficient amounts by ordinary bread. Foods described as poor in lime are bread, meat, and potatoes, while rice, lentils, cabbage, cherries, figs, strawberries, egg yolks, and milk are considered rich in this substance.

Report to the local government board upon the "biological properties" of milk, both of the human species, and of cows, considered in special relation to the feeding of infants, JANET E. LANE-CLAYTON (*Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., n. ser., No. 76* (1913), pp. 95).—The ferments and so-called "protective substances" (precipitins, agglutinins, etc.) present in milk together "form the group of so-called 'biological substances' in contradistinction to the more tangible chemical substances (sugar, protein, fats, salts, and water) which constitute the directly nutritive part of milk. . . ." The aim of this report is to investigate the presence of the biological substances; to discover how far they are due to bacterial contamination, and how far they are present in milk as such, apart from the contained bacteria; further, to endeavor to determine whether such substances can be considered to be of value to the infant, in aiding, or bringing about the digestion of the food material of milk itself, or in producing immunity from the disease.

The following statements are taken from the general summary and conclusions which the author makes after an exhaustive survey of the literature of the subject and from original clinical and experimental observations: "Most of the ferments . . . are derived from the bacteria which are found in milk. There is no evidence to show that uncontaminated milk contains any ferments capable of assisting in the digestion of food by any of the processes of digestion at present known to us. The only ferments present in uncontaminated milk are those which are well known to be present in large quantities in the blood,

and ferments (whose presence is not firmly established) which act upon substances not known to occur in the processes of digestion.

"In milk, the content of ferments which are similar to those which occur in the blood is found to be increased in quantity at periods when the mammary gland is not in a condition of good working activity; such as at the beginning and end of lactation, in mastitis, and in the case of poorly acting glands.

"It is . . . universally conceded that milk from a gland in these conditions contains exudate from the blood; the healthier the gland the less the exudate. It follows, therefore, that the traces of such ferments as are found in the milk under normal conditions, are present because they have passed out from the blood either by filtration or exudation. A precisely similar explanation holds good for the presence in milk of substances concerned in the production of immunity. . . .

"The value of these materials to the infant evidently depends upon the degree of absorption which takes place from its alimentary canal. . . . It appears that absorption of protein and hence of the immune substances which are attached to the protein molecule may take place directly during the first few days of life. This capacity is, however, of very short duration, especially for foreign protein, which must be broken down before it can be absorbed.

"The oft repeated assertion of the value to the infant of raw cow's milk fades away when the facts are examined, since, in cow's milk it is found that these so-called 'biological substances' are not absorbed in the alimentary canal but are destroyed there.

"These considerations also explain the results obtained by those who have investigated the comparative nutritive properties of the raw and boiled milk of a foreign species; these results were fully summarized by me in a recent report to the local government board (E. S. R., 30, p. 760), and it was shown that in dealing with the milk of a foreign species, boiled milk gave perhaps slightly better results than raw milk. In dealing with the milk of a foreign species the real question at issue is that of the chemical changes which take place on heating. . . .

"If the milk of the same species be now considered, a somewhat different aspect is put upon the whole question, because there appears to be some degree of evidence that native protein is absorbed as such, for a longer period than foreign protein. The transitory nature of immunity procured by the suckling does not, however, lead to the supposition that this occurs to any extent, and the evidence all goes to show that the amount of protein which is absorbed as such at any time forms only a small part of the total amount present.

"The question finally resolves itself into the chemical value of the food material, and it is this fact which brings about the difference commonly observed between the condition of the average breast-fed baby and the average artificially fed infant. . . . Considering for a moment the almost certain absorption of protein during the first few days of life it would appear to be very important that the organs should receive native protein. Without entering upon the much discussed question of the effect on the infant of the introduction into the blood stream soon after birth of foreign protein, the mere fact that precipitins are formed by the organism upon the introduction of foreign protein for the express purpose of throwing these substances out of action, would of itself seem to indicate that their presence is not desirable. It has been stated that the injection of foreign protein calls forth less resistance in quite young animals than in older ones, but this probably does not mean that such substances are harmless, but that the organs are not yet sufficiently mature to be able to form precipitins. It has been shown by Schlossman and Moro that the proteins of human milk and of human blood are biologically identical, hence

the absorption of native protein brings about no disturbance to the young organism, but rather supplies it with ready-made food material, and may thus act as a stimulus to development. . . .

"The investigation of the biological properties of milk carried out in this report shows that the weight of evidence suggests the absence of any direct value in the biological substances, per se, but it also most decidedly shows the paramount importance of providing breast milk for the young animal. It would seem impossible to emphasize this fact too strongly, and all those concerned in the health of infants should aim at obtaining satisfactory breast feeding for all infants during, at any rate, the early weeks of life."

A note on the relation of different milks to infantile scurvy and beri-beri is appended, as is also an extensive bibliography.

Present knowledge regarding the putrefaction of butcher's meat, E. GRIMALDI (*Mod. Zoologia, Parte Sci., No. 11 (1913), pp. 469-479*).—A summary of recent studies and theories concerning putrefied meats and the danger of using them for food. The importance of more careful inspection of all meat is urged on the ground that many forms of dangerous putrefaction are not recognizable by the senses.

The nitrogen content of mince-meat, C. A. A. UTT (*Amer. Food Jour., 8 (1913), No. 11, pp. 464, 465*).—On the basis of analyses of mince-meats made in the laboratory of the Kansas state food analyst, the author discusses the present federal definition of mince-meat and the recipes in common use, and suggests that the standard be so modified that instead of "not less than 10 per cent of cooked, comminuted meat", the requirement read "meat present in sufficient quantity so that the total nitrogen of the mince-meat is not less than 0.50 per cent", this nitrogen being the equivalent of about 5 per cent of meat.

Meat extracts, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul., 267 (1913), pp. 23*).—Reports of analyses of 80 samples of meat extract purchased in the open market in Canada during February and March, 1912, are here given. Of these, 12 were classified as solid meat extracts, 25 as normal meat extracts, 42 as fluid meat extracts, and 1 as meat juice.

Notes on the history of preserving fish, T. A. L. BEEL (*Ztschr. Fleisch u. Milch-hyg., 24 (1913), No. 6, pp. 129-133, figs. 3*).—A descriptive article dealing with the herring industry.

Conserving the nitrogenous material in dried codfish (*Gadus brandtii*), K. YOSHIMURA and M. KANAI (*Hoppe-Seyler's Ztschr. Physiol. Chem., 88 (1913), No. 5, pp. 346-351*).—The nitrogenous constituents identified included 13 gm. taurin, 1.4 gm. creatinin, and less than a gram of betain, methylguanidin, and alanin per kilogram of dry material. A little glutaminic acid was found but no creatin or cholin.

Investigation of reprocessed canned salmon—possible danger from its use as a food (*Amer. Food Jour., 8 (1913), No. 11, p. 462*).—This note from the laboratory of the state chemist of Washington deals with a type of canned salmon known to the trade as "do-overs." Cans processed as usual which, after a few days, show signs of swelling are frequently disposed of to brokers who puncture and reprocess them and sell the material so treated under labels which give no indication of their origin. Laboratory examination of such goods shows that the contents may or may not be rendered sterile by the reprocessing and that in some cases material already decomposed is sterilized and sold. The danger of poisoning from such reprocessed salmon is pointed out.

Dried and packaged fruit, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 269 (1913), pp. 25*).—This bulletin reports analyses of 175 samples of dried fruits, bought in the open market in Canada, which include raisins, currants, prunes, figs, dates, apples, apricots, peaches, and pears, 83 being obtained from

broken bulk packages and 92 from packaged fruit. Of these, 138 were found satisfactory, 20 doubtful, and 17 adulterated,

Preserves, E. COLLIN (*Ann. Falsif.*, 6 (1913), No. 62, pp. 629-638, figs. 3).—The results of microscopical studies are reported with reference to the examination of preserved fruits.

The digestibility of the nitrogenous material in cocoa and cocoa shells, S. GOR (*Biochem. Ztschr.*, 58 (1913), No. 1-2, pp. 137-147).—Experiments showed that roasting lowered the digestibility of the nitrogenous material of cocoa, the amount being proportional to the time of roasting and the temperature. The author's recommendation is accordingly made that roasting should be carried only far enough to develop the desired aroma.

Marked differences were noted in the digestibility of the protein of different sorts of cocoa, the coefficients of digestibility of total protein ranging from 45.62 to 72.45 per cent. Considerable variations were also noted in the digestibility of the protein of cocoa shells, the highest range being from about 48 to 58 per cent in the different samples.

Celery seed, A. JUILLET (*Ann. Falsif.*, 6 (1913), No. 62, pp. 671-674, figs. 2).—Histological data are given with reference to the identification of celery seed in materials used as seasoning.

The complete official proceedings of the 17th annual convention of the Association of American Dairy, Food, and Drug Officials, at Mobile, Alabama, June 16-20, 1913 (*Amer. Food Jour.*, 8 (1913), No. 7, pp. 195-298, pl. 1, figs. 39).—This contains the full report of the sessions of this meeting of the association together with the papers and discussions there presented.

Report of the Commonwealth and States of Australia, second conference on uniform standards for foods and drugs (*Melbourne: Govt.*, 1913, pp. 47).—As a result of the conference general recommendations are made for standards and regulations regarding labels, preservatives, flavorings and colorings, packages and containers, poisonous metals in foods, and other related topics. The numerous specific regulations formulated have to do with flour, bread and meals, vegetables, meats, milk and milk products, condiments and spices, and so on, as well as some drug products and soaps. Especially noteworthy are the regulations for the protection of food from contamination and the large amount of attention paid to this subject.

The new cookery, LENNA F. COOPER (*Battle Creek, Mich.*, 1913, pp. 9+298, pls. 5).—This volume is made up very largely of recipes and directions for preparing breads, soups, entrées, desserts, and other dishes. Milk and some milk products, eggs, and some commercial meat substitutes and other commercial goods are mentioned in addition to vegetable products, but the recipes do not include meat and meat products.

Some menus of meals made up of the kinds of food referred to in the book are appended, and there is an introductory chapter briefly referring to theories of nutrition from the standpoint of one who believes in low proteid and lacto-vegetarian diet.

Cooking by G. A. S., compiled by HELEN EDDEN, edited by MRS. M. A. C. BRERETON (*Westminster, [London]*, pp. 126, figs. 20).—Ways in which gas can be used in cookery are discussed and directions for using gas for such purposes are given, together with a large number of recipes suitable for gas cookery and some suggestions for quickly cooked meals and a number of menus.

[Electricity for cooking and heating] (*Jour. Gas Lighting*, 125 (1914), No. 2643, pp. 21, 22).—A review is given of the progress in such uses of electricity during the past year.

The value of sanitation as applied to railway and other large corporations, M. C. THURSH (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 14, pp. 1286-1288).—In

this article, which makes definite recommendations regarding railway sanitation, attention is to be paid to the need for supervision of the health and physical condition of employees concerned with the preparation and service of food, measures which shall insure sanitary conditions in providing water supply on railroad trains, and similar topics, in order that cleanliness may be insured and the possible spread of disease prevented.

Healthy employees in kitchen and dining room, G. HOMAN (*Jour. Amer. Med. Assoc.*, 60 (1913), No. 19, p. 1479).—A discussion based on the article abstracted above, endorsing the sanitary measures proposed.

Clean hands [in relation to food sanitation] (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 17, pp. 1542, 1543).—This is a brief summary of data in which are pointed out the danger of conveying disease (typhoid fever) by contact of soiled fingers with food and the need for supervising the health of persons who prepare and handle food. "The supervision of cooks and waiters in dining cars, hotels, restaurants, and clubs is certainly a matter that deserves more attention than it has yet received."

Notes on the increased cost of living, A. DUCKWORTH (*Rpt. Austral. Assoc. Adv. Sci.*, 13 (1911), pp. 505-507).—In this discussion of the subject with reference to Australasian conditions, the author notes that the increased cost of living in recent years has been variously estimated at from 10 to 25 per cent in Australia and that the rise in New Zealand has been equally pronounced.

Domestic economy—the family budget, G. FLETCHER (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 4, pp. 735-739).—In this excerpt from a paper read at the Twelfth Annual Congress of the Irish Technical Instruction Association the importance of family budgets is insisted upon and a plan proposed for securing a detailed family budget regarding the household of the Irish artisan living in an urban center.

Studies from the department of physiology, II (*Cornell Univ. Med. Bul.*, 3 (1913), No. 1, pp. 220, pls. 4, figs. 7).—This collection of 12 reprints from current periodicals describes work of G. Lusk and his associates, done in 1912-13 in the physiological laboratory of Cornell University Medical College, and is mainly concerned with the results of experiments made with the respiration calorimeter. See also previous notes (*E. S. R.*, 30, p. 365.)

Concerning the absolute vegetarian diet of Japanese monks, III, IV, G. YUKAWA (*Arch. Verdauungskrank.*, 19 (1913), No. 3, pp. 356-370; *abs. in Zentbl. Expt. Med.*, 4 (1913), No. 10, p. 445).—To secure further data, the author made 2 more experiments, each with 2 Buddhist monks as subjects. Rice of the best quality was used instead of rice collected from various sources, as in his experiments previously reported (*E. S. R.*, 23, p. 372).

In the first of these experiments, the subjects, aged 38 and 28 years, and weighing, in round numbers, 53 and 48 kg., respectively, did no muscular work. The diet, which consisted of rice and barley, supplemented by soy bean products and similar materials, contained on an average 67 gm. protein and 2,099 calories, or 39.54 calories per kg. of body weight. Full details regarding these subjects are not reported.

In the second of the tests the subjects were 25 and 21 years old, weighing, in round numbers, 54 and 51 kg., respectively. These subjects performed some muscular work, including walking. Soy bean products with vegetables and similar foods were used with the rice, which was the principal article of diet. Foods and excretory products were analyzed, phosphoric acid and sodium chlorid being determined in the urine as well as nitrogen and specific gravity. The daily diet of one of these subjects contained 76 gm. protein, 16 gm. fat, and 587 gm. carbohydrates, and of the other, 63 gm. protein, 14 gm. fat, and 471 gm. carbohydrates. The energy values were 2,864 calories and 2,320 calories,

respectively. The diet supplied on an average 69 gm. protein and 2,592 calories of energy, or 46.4 calories per kg. of body weight.

From this experiment the author draws the same conclusion as formerly, namely, that the absolute vegetarian diet of the Buddhist monks studied, which had a minimum energy value, sufficed for maintaining health. The fact that the whole body, and particularly the digestive apparatus, was accustomed to such a diet is regarded as of special importance.

The rate of elimination of nitrogen as influenced by diet factors.—**I, The influence of the texture of the diet; II, The influence of carbohydrates and fats in the diet; III, The influence of the character of the ingested protein,** L. B. MENDEL and R. C. LEWIS (*Jour. Biol. Chem.*, 16 (1913), No. 1, pp. 19–36, figs. 9, 37–53, figs. 9, 55–77, figs. 12).—This work includes the results of a long series of digestion experiments with laboratory animals (dogs) in which the effects of a standard diet are compared with those of similar diets modified as indicated by the subtitles. The authors summarize the work as follows:

“Apart from the character of the protein ingested a large number of diet factors—the water intake, the presence and nature of indigestible materials in the diet, the amount and character of the carbohydrate fed, and to some extent the presence of fat in the diet—play a rôle in modifying the rate of elimination of nitrogen after a meal containing protein. With most of the proteins studied the nitrogen output curves differed to only a slight extent from one another; and in no case did the nature of the protein have a greater effect on the rate of nitrogen elimination than some of the nonprotein diet factors mentioned above.”

On the variations in the excretion of endogenous uric acid produced by changes in diet, G. GRAHAM and E. P. POULTON (*Quart. Jour. Med.*, 7 (1913), No. 25, pp. 14–28; *abs. in Zentbl. Biochem. u. Biophys.*, 15 (1913), No. 23, pp. 910, 911).—In metabolism experiments with normal subjects living on purin-free diets, it was found that the amount of uric acid excreted varied with the character of the diet. When protein and fat were given in quantities insufficient to supply the energy requirements of the body, the excretion of endogenous uric acid decreased 30 to 50 per cent. A similar effect was noted during the first day of a fasting experiment and also with a carbohydrate and fat diet. The most probable explanation seems to the authors to be found in the alternating action of protein and carbohydrate metabolism.

The alleged excretion of creatin in carbohydrate starvation, G. GRAHAM and E. P. POULTON (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1914), No. B 594, pp. 205–220, fig. 1).—According to the authors' conclusions, a carbohydrate-free diet did not cause the excretion of any creatin. Experimental methods are critically studied.

On fat absorption.—**III, Changes in fat during absorption,** W. R. BLOOR (*Jour. Biol. Chem.*, 16 (1914), No. 4, pp. 517–529).—Continuing previous work with dogs (E. S. R., 29, p. 768), the author notes the following changes in fats during absorption:

The melting point of high melting point fats is lowered by the addition of an unsaturated fatty acid, probably oleic. The melting point of a low melting point fat (olive oil) is elevated and the iodine number is lowered by the addition of saturated fatty acids. Fats consisting mainly of glycerids of saturated fatty acids (coconut oil) undergo no change of melting point by the addition of “oleic acid” accompanied by a change in their molecular weight. The iodine number of fat containing a large percentage of glycerids of highly unsaturated fatty acids (cod liver oil) is lowered.

“The intestine appears to have the power to modify radically the composition of the fats during absorption. The changes are apparently purposive in that

they vary in kind and degree with the nature of the fat fed, and also show in general a tendency toward the production of a uniform chyle fat, presumably the characteristic body fat of the animal."

It is suggested that one purpose of the peculiar mechanism of fat absorption is to permit such adaptive changes. The work is being continued.

Further experiments concerning normal and pathological digestion in dogs. E. S. LONDON ET AL. (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 81 (1912), No. 5-6, pp. 369-438).—In this article are brought together 15 papers by London and associates reporting details of extended and valuable investigations on digestibility made with laboratory animals (dogs). For an adequate understanding of the work, the original papers should be consulted.

Studies of growth.—I, Growth with food containing vitamin and with vitamin-free food. C. FUNK (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 88 (1913), No. 5, pp. 352-356, No 1).—The laboratory animals selected for these experiments were chickens, as, according to the author, they resemble man with respect to the effects of vitamin-free diet.

In general, the results showed that chickens did not grow even when the food (polished rice) supplied a vitamin, and so it appears that the vitamin needed for growth is not identical with the vitamin which prevents beri-beri. According to the author, recent experiments indicate the theory of a specific growth-stimulating substance not in the food. The substance is presumably present in a negative form and becomes active through the agency of certain glands, probably the hypophysis.

The report contains a brief reference to the effect of vitamins on mammalian groups, a subject which the author is also investigating.

Studies on pellagra.—I, The influence of the milling of maize on the chemical composition and the nutritive value of maize-meal. C. FUNK (*Jour. Physiol.*, 47 (1913), No. 4-5, pp. 389-392, fig. 1).—The close resemblance of pellagra to other deficiency diseases (beri-beri and scurvy) led the author to formulate "a new hypothesis which regards pellagra as due to a lack of vitamins in the food."

In addition to the ash constituents, amino nitrogen with the corresponding melanin nitrogen, phosphorus, fatty acids, cholesterol, and lipid phosphorus were determined in whole maize grain, highly milled meal representing 86 per cent of the grain, and its bran in 2 fractions, (namely, the first milling, which consisted of the skin with a part of the superficial aleurone layer, and the second milling, which represented the main part of the aleurone layers and the germ). Specially ground, slightly milled meal deprived of the skin with a little adjacent layer, which represented 97 per cent of the entire grain, and the corresponding bran were also analyzed. Besides the analyses enumerated, the different samples were tested for the color developing with the phosphotungstic-phosphomolybdic reagent.

"The results obtained show beyond doubt that the distribution of vitamins in the grain of maize resembles closely that of rice. . . . [The analytical data show] that highly milled maize is deprived of some important constituents, such as phosphorus, both the total and the lipid phosphorus and also fat. This meal is also deprived to a great extent of the substance giving the color reaction. On the other hand we see that the millings which are thrown away or given as food for cattle are extremely rich in all constituents. From the analytical data we can say that there are four distinct layers in the maize grain. First the external layer, the skin, very poor in all constituents, underneath which is a layer which gives the above mentioned color reaction, then a third layer (included in which is the germ) extremely rich in proteins, fat, lipoids and salts; finally the fourth layer, the starch endosperm."

The author points out reasons for believing that products very rich in vitamin should show a difference in nitrogen when analyzed by the Dumas and the Kjeldahl methods. Analyses showed that "the fraction of the maize grain which contains the skin with adjacent layer gives in reality a considerable difference in the content of nitrogen, the Dumas method giving much higher results than the Kjeldahl method. This difference, however, is due very likely to the presence of methane, a decomposition product of methoxylated cellulose derivatives."

Similar tests with yeast led to the conclusion that although this "is so rich in vitamins, the amount of vitamin nitrogen to the total nitrogen must be a negligible quantity. Whether concentrated vitamin extracts will give a perceptible difference or not future investigations will determine.

"As regards the color reaction, which is without any doubt due besides to the presence of vitamins to an admixture with other substances, its value at present is limited; we notice, however, that the meal extracted in heat with alcohol yields comparatively less color than the meal extracted in cold. This suggests that heating diminishes the content of color-giving substances to some extent."

In his summary the author points out that, from the observed differences in the chemical composition of the four distinct layers of the corn kernel, "it would seem probable that the vitamins are distributed in the external layers of the grain. This explains why according to the mode of preparation of maize-meal in different countries the manifestations of pellagra vary from mild to severe forms.

"We are not able to say at the present moment which of the three external layers is more likely to contain the bulk of the vitamins. Besides vitamins the grain is deprived during the process of milling of a great quantity of salts, proteins, fat, and lipoids.

"The result of this investigation is that for the present moment it would be advisable to abandon the present mode of milling since only the whole grain including the skin can be regarded as a complete food."

It is the author's intention to test his theories by means of laboratory experiments with animals.

The physiological value of certain hitherto unknown constituents of foods, the vitamins, C. FUNK (*Ergeb. Physiol.*, 13 (1913), pp. 125-205, pl. 1, figs. 5).—A summary and discussion of the author's extended experiments, including work noted on page 865.

Studies on water drinking: XIII, Fasting studies.—VIII, Hydrogen ion concentration of feces, P. E. HOWE and P. B. HAWK (*Jour. Biol. Chem.*, 11 (1912), No. 2, pp. 129-140).—The hydrogen ion concentration of the feces of 3 men was determined, 2 in a series of water drinking experiments and the third in a fasting test, as well as in preliminary and final periods.

According to the authors, "the reaction of the feces was uniformly alkaline, the hydrogen ion concentration varying between 0.15×10^{-8} and 9.8×10^{-8} . As the result of water drinking with meals there was a tendency for the hydrogen ion concentration to increase. Pronounced changes in the dietary régime, such as high protein, low protein, and fasting did not affect the hydrogen ion concentration of the feces sufficiently to cause other than small variations in the uniformly alkaline reaction. As the result of fasting, the stools were alkaline in reaction (hydrogen ion concentrations of 1.4×10^{-8} and 0.94×10^{-8}) as opposed to the acid stools reported by previous investigators. The hydrogen ion concentration differs for the feces of different individuals living on the same diet."

Fasting studies.—IX, On the differential leucocyte count during prolonged fasting, P. E. HOWE and P. B. HAWK (*Amer. Jour. Physiol.*, 30 (1912),

No. 2, pp. 174-181).—As the authors point out, changes in the distribution of various forms of leucocytes in the blood during prolonged fasting have received little attention from investigators. The majority of observations have been confined to the enumeration of the erythrocytes and leucocytes and the estimation of the hemoglobin.

According to the author's conclusions, the data obtained in the case of 2 fasting men indicate an increase in the percentage of the polymorphonuclear leucocytes at the beginning of the fast, followed by a decrease below the normal at the end of 7 days; the opposite conditions held for the lymphocytes. An increase in the percentage of large lymphocytes during the earlier part of each fast was noted. One of the subjects showed an increase in the eosinophilic leucocytes which continued through the post-fastings feeding period. When food was taken after fasting a tendency was noted for all the forms of leucocytes to return to the normal.

Fasting studies.—X, A note on a glycogen-free liver, P. B. HAWK (*Jour. Amer. Chem. Soc.*, 34 (1912), No. 6, pp. 826-828).—Dog liver and a portion of muscle were examined for the presence of glycogen after fasting for periods of 117 and 104 days respectively (E. S. R., 27, p. 465). None was found.

The relation of the feeling of fatigue to the CO₂ output during static muscular work, K. FRUMERIE (*Skand. Arch. Physiol.*, 30 (1913), No. 4-6, pp. 409-437, figs. 5).—The experiments here reported were made with apparatus devised by Johansson (E. S. R., 13, p. 580; 14, p. 789) and the Tigerstedt-Sonden respiration chamber. Under the conditions of the experiments there appeared to be no relation between the output of carbon dioxide and the feeling of fatigue, but the oncoming of the latter bore definite relations to the character of the muscular contractions, and the pain which accompanied its later stages was attributed to the mechanical irritation of the corpuscular nerve ends in muscles, sinews, joints, and periosteum.

ANIMAL PRODUCTION.

The calcium and phosphorus supply of farm feeds, and their relation to the animal's requirements, E. B. HART, H. STEENBOCK, and J. G. FULLER (*Wisconsin Sta. Research Bul.* 30 (1914), pp. 28, figs. 2).—On the basis of figures obtained mainly from Wolff's tables of plant ash analyses and of previous results obtained at the Rothamsted Station and elsewhere on the calcium and phosphorus requirement of swine and ruminants it is concluded that "grains are deficient in calcium, but rich in phosphorus. Rations wholly made up of grains will supply to the growing animal an amount of calcium dangerously near a critical level of intake.

"Swine, growing or breeding, and confined wholly to grain rations should receive an additional supply of calcium either as calcium carbonate, calcium phosphate, or legume hay.

"The roughages vary widely in calcium content. The straws contain the least, while legume hays are very rich in calcium. Ruminants and the horse consuming the usual roughage will ordinarily receive calcium enough for growth. This is especially true when the roughage has been grown on a calcium-rich soil.

"For continued and high milk production, with its extra drain of calcium, the supply may be dangerously low unless legume hays form a part of the ration or calcium is furnished in other forms. When grain forms a liberal part of the ration the supply of phosphorus will be abundant under almost all conditions of animal life."

The results of metabolism experiments carried on with swine indicate that the addition of calcium carbonate or calcium phosphate to grain rations increases the retention of both calcium and phosphorus and results in the formation of a heavier skeleton.

"The relative efficiency of calcium carbonate and calcium phosphate in increasing the retention of phosphorus depends in a measure upon the amount of phosphorus present in the grain. The addition of calcium carbonate to a grain ration increases the calcium and decreases the phosphorus in the urine.

"The addition of calcium phosphate does not influence the amount of calcium and does not always influence the amount of phosphorus excreted in the urine. Additional calcium supplied to growing swine increases the size of the shaft of the bone, but the length or rate of growth is not influenced.

"High calcium rations, as compared with low calcium rations, had no effect whatever during a single gestation period on the size or calcium content of the skeleton of the fetus. The skeleton is not increased in any dimension by a wide variation in the amount of calcium fed the mother."

Studies of the natural pasture grasses of Uruguay, J. PUIG Y NATTINO (*Rev. Min. Indus. Uruguay*, 1 (1913), No. 3, pp. 82-97).—The composition, distribution, and relative feeding value of 20 of the natural pasture grasses of Uruguay are reported. These include orchard grass, rescue grass, meadow fescue, rye grass, wild oats, plantain, blue joint, and others.

Sugar-beet pulp for feeding live stock (*Jour. Bd. Agr. [London]*, 20 (1913), No. 9, pp. 784-793).—This is a review of English, German, and American experiments in feeding sugar-beet pulp to various classes of farm stock.

Commercial feeding stuffs, J. P. STREET (*Connecticut State Sta. Rpt. 1913*, pt. 5, pp. 309-351).—Analyses are reported of the following feeding stuffs: Cotton-seed meal, linseed meal, wheat bran, gluten meal, hominy feeds, corn meal, rye middlings, buckwheat middlings, malt sprouts, dried brewers' and distillers' grains, alfalfa meal, dried-beet pulp, molasses feed, ground corn-stalks, corn kernels, beef scrap, ground brush, cocoa siftings, peanut hearts, bakery refuse, North Carolina grass, meadow hay, and various mixed and proprietary feeds. There are also included data showing short weights on bagged feeds and a table giving the average composition of 436 fodders and feeds analyzed at the station, 1878-1913.

Commercial feeding stuffs of Pennsylvania in 1912, J. W. KELLOGG ET AL. (*Penn. Dept. Agr. Bul. 234* (1913), pp. 227).—The average analysis and retail price of the following feeding stuffs are reported: Cotton-seed meal, gluten meal, linseed meal, distillers' grains, brewers' grains, buckwheat middlings, malt sprouts, wheat middlings, low-grade flour, rye middlings, corn-oil meal, wheat bran, molasses feed, alfalfa meal, hominy feed, corn bran, dried beet pulp, oat hulls, meat scrap, and various mixed and proprietary feeds.

Animal economy section (*X. Cong. Internat. Agr. Gand, 1913, Compt. Rend.*, pp. 241-257).—This is merely the minutes of this section of the congress, recording the papers and discussions relating to animal economy that came before that body, as previously noted (*E. S. R.*, 29, p. 104).

Division of animal husbandry (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 12, pp. 595-602, 591-593, pls. 2).—Feeding experiments with swine indicate that the substitution of papaya for a portion of grain ration materially increases daily gains, although an entire ration of papayas was not satisfactory.

The results of a test with kapok seed meal indicate that it may be used to form a valuable adjunct feed for cattle, although it is a fat rather than a muscle producing feed and could perhaps be used more advantageously in finishing cattle for market than for the feeding of work cattle. When fed to swine it was found that the meal had a poisonous effect.

Progress reports are given of the horse, cattle, swine, goat, and sheep projects under way at the several stations. It is reported that the pure-bred Nellore herd of cattle has thrived in spite of a dry season and sparse pasture conditions. Hereford grades from Chinese dams produced during the year very promising calves, showing characteristics of the sire to a marked degree; the only objection to these offspring was the slight woolly coat which makes them liable to tick infection. An objection to the Nellore breed is its extreme legginess and rangy body conformation. The grades seem to be much blockier or beefy, more docile, earlier maturing, and apparently better rustlers. They are much larger than the native or Chinese dams and are immune or highly resistant to rinderpest.

The Berkshire breed has proved well adapted for the upgrading of the native swine; the first cross shows a preponderance of the pure-bred characteristics and appears practically as well adapted to local conditions as the native stock.

Studies on the prehistoric Moravian cattle, F. MOHAPL (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 2 (1913), No. 1, pp. 75-97, pls. 4).—As the result of studies and skeletal measurements of the prehistoric cattle of Moravia the author concludes that these cattle were of either the *Bos frontosus* or *B. brochyccephalus* type, and disagrees with Werner in his statement that they were of the *primigenius* race.

The Flemish breed of cattle, H. RAQUET (*Rev. Min. Indus. Uruguay*, 1 (1913), No. 4, pp. 40-53, figs. 15).—This article treats of the breed characteristics and utility value of the Flemish breed of cattle, and discusses the importation and adaptability of the breed to Uruguay conditions.

Studies on Hannaberner cattle, F. MOHAPL (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 2 (1913), No. 1, pp. 99-174, pls. 4).—A study was made of the body characteristics and skeletal measurements of the Hannaberner cattle of Moravia and comparisons made with those of the Simmentaler and other types of Northern Europe.

Studies on the Irish-Kerry cattle, E. LUNDWALL (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 2 (1913), No. 2, pp. 331-374, pls. 10).—A study of the body characteristics and skeletal measurements of the Kerry cattle of Ireland, with comparisons of those of the Bretagne and Polish Red cattle. There is given an account of the crossing of the Kerry and Dexter cattle, forming a breed known as the Dexter-Kerry. It is believed that the original cattle were of the brachycephalous type.

White cattle of Italy, N. B. STEWART (*Daily Cons. and Trade Rpts. [U. S.]*, 17 (1914), No. 24, p. 384).—It is stated that the white cattle which predominate in northern Italy are of the Piedmont breed and are particularly suitable as work animals. The Piedmont bull weighs from 2,200 to 2,400 lbs., while the cow weighs from 1,200 to 1,550 lbs. There are several other breeds of white cattle in Italy. None of these has been exported to North America.

Inbreeding and heredity studies with cattle of the West Prussian herd book, G. HESSE (*Arb. Deut. Gesell. Züchtungsk.*, No. 18 (1913), pp. VI+215).—This reports extensive studies made of the blood lines of 3 prominent herds of cattle in West Prussia to determine the relative influence of inbreeding upon offspring. It is concluded that the prospects of success with inbreeding are most propitious, provided systematic methods are employed.

Experiments in steer feeding in Manitoba, W. C. MCKILLICAN (*Canada Expt. Farms Bul.* 13, 2. ser. (1913), pp. 21, fig. 1).—The principal conclusions of the work reported in this bulletin, which is a summary of tests conducted at the experimental farm at Brandon, Manitoba, from 1892 to 1912, and for the most part previously noted, are as follows:

Good results can be obtained with straw and grain, although the addition of roots or silage improves a ration. Hay and oat sheaves give larger gains than straw. Steers fed loose in a box stall do better than when tied. Dehorning gives little or no setback and makes loose feeding practicable. While steers may be fattened successfully outdoors in winter in Manitoba if sheltered from the wind, somewhat greater gains may be secured if fed in a stable. The advantage of feeding oats, barley, or low-grade wheat to steers over marketing through the elevator was demonstrated.

Cattle-feeding experiments, W. BRUCE (*Edinb. and East of Scot. Col. Agr. Rpt. 31 (1913), pp. 16*).—This is a continuation of work previously noted (E. S. R. 29, p. 272). Three lots of 16 steers each, weighing approximately 825 lbs., were fed for a period of 133 days on the following average daily ration per head: Lot 1, 3.95 lbs. linseed cake, 3.78 lbs. Bombay cotton cake; lot 2, 5 lbs. bran, 3.78 lbs. cotton cake; and lot 3, 7.73 lbs. of a mixture consisting of cotton cake, bran, linseed cake, decorticated cotton cake, and maize meal, 2:3:1:1:1. In addition all the lots received an average daily allowance of 102 lbs. swedes and 7.78 lbs. oat straw per head.

It is estimated that lot 1 received 14.19 (Kellner) starch equivalents daily; lot 2, 13.7; lot 3, 14.12; and that the balance available for fattening purposes after 6 units were deducted for maintenance was in the proportion of 100:94.01:99.08 for the respective lots. The average daily gain was in the proportion of 100:98.8:100.13.

The total gain in weight per head was for lot 1, 270.4 lbs.; lot 2, 267.3 lbs.; and lot 3, 270.8 lbs. In dressing percentages the bran-fed lot was 0.9 per cent higher than the other lots, the result conforming to results in former trials.

The sheep of Bosnia and Herzegovina, M. MEHMEDBASIC (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien, 2 (1913), No. 2, pp. 307-330*).—This reports studies on the body characteristics, skeletal measurements, and milk, wool, and mutton utility value of the sheep of Bosnia and Herzegovina (*Ovis strepsiceros*).

Fecundity of sheep, J. R. AINSWORTH-DAVIS and D. TURNER (*X. Cong. Internat. Agr. Gand, 1913, Sec. 3, Question 4, pp. 5*).—With the object of testing the extent of inheritance of the "twinning faculty" in sheep, 12 Oxford Down twin ewes were secured by the Royal Agricultural College, Cirencester, and bred to a pedigree Oxford Down ram twin. Six of the ewes were mixed twins, i. e., one of each sex; and 6 were ewe twins, i. e., both females.

From the 3 seasons during which the trials were conducted "all the twins produced in 1910 and 1911 were born by the ewes from mixed twins. This was not confirmed, however, in 1912. The twins were mostly mixed, and there was no case of ram twins in the 3 years. The ewes of lot 1 (mixed twins) produced throughout, taking twins and singlets together, a much higher percentage of ewe lambs than ram lambs. The ewes of lot 2 (ewe twins) gave birth to a much higher percentage of ram lambs."

Due to the paucity of the experimental flock, no definite conclusions are to be drawn. However, the work is to be continued and the line of research broadened.

Annual wool review for 1913 with estimate of domestic wool clip of 1913 and other statistical tables, W. J. BATTISON (*Bul. Nat. Assoc. Wool Manfrs., 44 (1914), No. 1, pp. 1-63, pl. 1*).—This is a résumé of the present wool situation in the United States, with special reference to the effects of the Simmons-Underwood tariff act which puts wool on the free list. Statistical data are given on the number of sheep for 1913; the wool product; fleece; pulled and scoured wool; value of wool products; exports and imports; the slaughter and movement of sheep; the course of prices; comparative prices of

domestic wool in Boston, 1899-1913; mohair production in the United States; imports of wool and wool manufacturers; London wool sales; Liverpool East India wool sales; Antwerp wool auctions; South American wool production; Australian wool and sheep statistics; South African wools; number of sheep in the world; and wool production of the world.

On the wild and domestic swine of the pile works in the Laibach moor and on the relation of these swine to an extinct race, S. ULMANSKY (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 2 (1913), No. 1, pp. 17-74, pls. 4).—After a very complete study of skeletal remains of prehistoric swine found around the pile works of the Laibach moor, the author concludes that the wild or turf swine occupy a middle position between the 2 species *Sus scrofa* and *S. vittatus*, and that the present-day wild swine of Bosnia Herzegovina represent a similar type. The relation of these swine to other more modern wild swine of Europe and Asia is discussed.

Brood sows and their litters, R. L. HILL (*Chicago*, 1913, pp. 80, figs. 25).—A practical book dealing with the feed, care, and management of the brood sow and her litter.

Studies of the body, heart, and lung weights of the improved native and Berkshire breeds of swine, A. SEMMLER (*Jahrb. Wiss. u. Prakt. Tierzucht*, 8 (1913), pp. 88-137).—In a study of the dressing weights and lung and heart capacities of swine it was found that male animals have a larger heart weight in proportion to live weight than female animals, and that heart weights of Berkshire swine are relatively smaller than of the native white swine. There was found to be a correlation between the size of heart and body weight, the larger heart being associated with greater weight, accounted for because of the greater blood circulation, thus aiding in the digestive process and in the assimilation of food. There was no relation between lung weight and lung capacity, the lightest lung weight not necessarily meaning a low capacity of volume.

On the average, large lung capacity is associated with greater live weight, and from these observations it is concluded that feeding and management methods should be so conducted as to be conducive to the growth of large lung capacity. It was observed that the lungs of young animals are relatively large; of fat animals in advancing age, small; and of breeding animals, large. Measurements made of the breadth and depth of the breast indicated that on the average large measurements are accompanied by large heart and lung weight and that these relationships are fairly constant. The length of body with advancing age is associated with greater lung and heart weight. Increasing height at the withers in fat swine was associated with smaller lung and heart weight, but in breeding animals with larger lung and heart weight.

There was found to be a large variation in the relation between the outer breast measurements and the lung capacity, depending upon age, breed, and individuality of animals. With advancing age the lung capacity of the female animal is proportionately larger than that of the male. The pure-bred Berkshire has a lower lung capacity than the improved native, and breeding swine a larger lung volume than castrated fat swine.

The author points out that the lung capacity depends upon the lung tissue and vesicles, rather than their weight, and concludes that it is impracticable to attempt to determine lung capacity by the size and exterior measurements of an animal.

Experiments with swine on the effect of nonprotein nitrogen compounds upon the nitrogen intake, A. KÖHLER (*Landw. Vers. Stat.*, 79-80 (1913), pp. 623-636).—A report of feeding experiments with the nonprotein nitrogen feeds asparagin and ammonium-acetate solution, in which it was found that the

nitrogen intake was lowered below normal when these substances were fed. This was in contrast to the results obtained when the proteid feed gluten was included in the ration, for in this case the nitrogen intake was materially increased.

The Missouri saddle horse, E. A. TROWBRIDGE, R. JACKSON, ET AL. (*Missouri Bd. Agr. Mo. Bul.*, 11 (1913), No. 10, pp. 95, figs. 35).—This bulletin contains articles on the following subjects: Recent saddle horse history in Missouri, the foundation of the present saddle horse industry in Missouri, saddle horses in Cooper County, Mo., and the American saddle horse and Americans, together with an account of the proceedings of the annual meeting of the Missouri Saddle Horse Breeders' Association, 1913.

Report of the stallion enrollment board of Ontario, 1913 (*Ann. Rpt. Stallion Enrollment Bd. Ontario*, 1 (1913), pp. 38).—This report contains an account of the history of the movement for the enactment of legislation on stallion registration in Ontario, the text of the Ontario laws and regulations, and a review of the present status of stallion registration in Canada and the United States, together with a table showing results of inspection for the Province of Ontario, 1912-13, with the causes for rejection.

Proceedings of the American Poultry Association (*Proc. Amer. Poultry Assoc.*, 38 (1913), pp. 319, pls. 3, figs. 72).—This contains a complete account of the proceedings of this Association with a list of members, association judges, and the official show rules.

Our domestic birds, J. H. ROBINSON (*New York, Chicago, and London*, 1913, pp. X+317, pl. 1, figs. 236).—This book deals with the feed, care, and management of our domestic birds, including chickens, ducks, geese, turkeys, guineas, peafowl, pheasants, swans, ostriches, pigeons, and canaries.

Farm poultry, W. R. GRAHAM and A. C. McCULLOCH (*Ontario Dept. Agr. Bul.* 217 (1913), pp. 64, figs. 48).—This bulletin treats of the following subjects: Poultry house construction, egg production, feeding methods, incubation, rearing chickens, fattening chickens, eggs for market, and breeds of poultry, together with short notes on poultry work in Ireland, Scotland, England, and Denmark.

The results of 3 feeding trials, involving 745 pullets, indicate that the average cost per dozen eggs produced ranges from 11.16 to 13.08 cts., the average cost of feeding each bird per month from 10.06 to 10.88 cts., the average grain consumption from 5.66 to 6.2 lbs., and the average milk consumption from 7.1 to 7.8 lbs. It was further found that where beef scrap was fed in a hopper or when the birds could eat all they desired, the Leghorns and Rhode Island Reds did much better than the Orpingtons; that with all 3 breeds buttermilk produced the most and the cheapest eggs; and that no animal feed in all instances gave the best eggs for hatching and the lowest egg yield. On a no-meat ration the feather eating habit was developed by the Leghorns, and to a limited extent by the Rhode Island Reds, but not by the Orpingtons.

Poultry keeping on the farm, F. S. COOLEY ET AL. (*Mont. Farmers' Bul.* 3 [1913], pp. 162, figs. 36).—This bulletin contains articles on standard varieties of chickens, studies in incubation in Montana, modern incubation and brooding, principles of breeding, double matings and breeding show birds, housing poultry, feeds and feeding, profitable egg production, market poultry, capons and caponizing, preparing fowls for exhibition, the decimal system of judging, turkeys, water fowl, guineas and ornamental fowl, squab breeding, and diseases and hygiene. A reprint of Farmers' Bulletin 357 of this Department (E. S. R., 21, p. 274) is appended.

Origin and early history of the primordial germ cells in the chick, C. H. SWIFT (*Amer. Jour. Anat.*, 15 (1914), No. 4, pp. 483-516, figs. 15).—This article

reports extended studies made into the origin and development of the primordial germ cells of the chick.

Electrified chickens.—Electricity as a growth stimulator (*Sci. Amer. Sup.*, 77 (1914), No. 1986, p. 63, figs. 4).—An account of the successful use of electricity as a growth stimulator in poultry. It is thought that the high frequency currents stimulate the blood circulation by lowering the viscosity of the blood. It is not at present known whether prolonged electric action increases growth up to maturity or whether its whole effect is to cause the maximum size to be sooner reached.

On the ability of chickens to digest small pieces of aluminum, MAYNIE R. CURTIS (*Maine Sta. Bul.* 221 (1913), pp. 314-318, figs. 3).—In examining the gizzards of chickens it was found that pieces of aluminum leg bands which had been picked up by the chickens were undergoing dissolution, evidently due to a combination of the mechanical grinding of the gizzard and the action of the hydrochloric acid of the gastric juice. In the cases examined it was estimated that the aluminum pieces had been in the gizzard not longer than 9 weeks and that the dissolution was about 25 per cent. It is noted that the aluminum salt formed (aluminum chlorid) is nonpoisonous. It was observed that the birds possess a considerable individuality in regard to the tendency to swallow pieces of bright metal.

The 300-egg hen, J. DRYDEN (*Country Gent.*, 79 (1914), No. 2, pp. 46, 70, figs. 3).—An account of the 2 champion egg-laying hens of 1913, which produced 303 and 291 eggs, respectively, in one year. These hens were fed and bred by the Oregon Experiment Station and are the result of selective breeding by that station for 6 years. Selection has been made both of pure breds and crosses, but the latter method has given the best results. All the high egg records have been secured from hens having high producers as ancestors.

The 2 hens were of similar breeding, Plymouth Rock and White Leghorn, and were fed and cared for similarly to other birds in a flock of 40. The 291-egg hen began laying at the age of 5½ months. Five sisters, including the 303-egg hen, averaged 246 eggs each. Five of the best layers in the yard averaged better than 280 eggs; 26 out of 40 exceeded the 200-egg mark, and the whole flock averaged more than 200. The total weight of eggs laid by the 291-egg hen was 36 lbs., and that of the 303-egg hen 42 lbs. The author contends that the problem of increasing the egg yield is one of selection and breeding and that it is founded upon the individual hen and not upon the flock or the breed.

Practical packages for egg marketing (*Orange Judd Northwest Farmstead*, 12 (1914), No. 6, p. 157, figs. 6).—A description of a number of egg-carrying cases, cartons, and boxes.

The Indian Runner duck book, C. S. VALENTINE (*Ridgewood, N. J.*, 1913, 3. ed., rev. and enl., pp. 166, pls. 12).—This book includes chapters on the origin, history, and development of the Indian Runner duck, the utility value of this breed, feeding methods, and the marketing of eggs.

Goose fattening in Germany, A. O. SCHILLING (*N. Y. Produce Rev. and Amer. Cream.*, 37 (1913), No. 8, 384).—An account of the German methods of growing goose livers. It is stated that "the forced or unnatural growth of the liver to an abnormal size renders it more tender and also causes it to be of a better flavor than a liver taken from a goose which has not been specially fed for this purpose."

"The geese are about 6 months old when they are ready for fattening. They are first put into an outside inclosure for 3 or 4 days and fed on boiled corn, the object being to accustom them to confinement gradually and also to

get them prepared for their regular diet during the fattening process. They are fed on boiled corn 4 times during 24 hours by the cramming machine process. The corn is boiled about one-half hour or until it is soft to the touch when squeezed between the fingers. This cramming process is carried on regularly for about 4 weeks, after which period the goose is usually found to be ready for killing. During the course of this artificial feeding the liver is caused to grow to an abnormal size, while the flesh becomes soft, tender, and white."

Goose livers produced by the cramming process usually weigh from 12 to 32 oz. White geese are preferred as it is said these fatten more easily.

Experiments with ostriches.—XXII, The development of the feather, showing absence of cruelty in clipping and quilling, J. E. DUERDEN (*Agr. Jour. Union So. Africa*, 6 (1913), No. 4, pp. 648-661, figs. 12).—A continuation of earlier work (E. S. R., 28, p. 270). In this the author describes the growth, development, and final ripening of the ostrich plume and shows wherein no cruelty is involved in the clipping and quilling operations.

Ostrich breeding.—The preparation and trade of the plume, A. MENEGAUX (*L'Élevage de L'Autruche. Récolte et Commerce des Plumes. Paris, 1913, pp. 156, pl. 1, figs. 27*).—This is a very complete treatise on ostrich breeding and management for commercial purposes. It includes a description of the several breeds of ostriches, a study of the structure and development of the plume, the methods of preparing plumes for commercial use, the points of quality desired in ostrich plumes, and the methods of harvesting the plumes. Methods in the domestication and breeding of the ostrich are described, and the probable growth of the industry in the Transvaal, Southeastern Africa, Australia, Algeria, Tunis, Sudan, Madagascar, Egypt, the United States, and other places discussed.

A pedigree system for use in breeding guinea pigs and rabbits, F. M. SURFACE (*Maine Sta. Bul. 221 (1913), pp. 306-313, figs. 4*).—Methods of marking guinea pigs and rabbits and of keeping pedigree and mating records and indexes in experimental breeding work are described.

Guinea pigs, W. E. CLARKE (*New York and Chatham, N. Y., 1913, pp. 47, figs. 9*).—A practical treatise on the breeding, feeding, and management of guinea pigs.

DAIRY FARMING—DAIRYING.

Soiling crops v. silage for dairy cows in summer, F. W. WOLL, G. C. HUMPHREY, and A. C. OOSTERHUIS (*Wisconsin Sta. Bul. 235 (1914), pp. 3-16, fig. 1*).—The results of trials to determine the relative value of soiling crops and of silage for dairy cows in summer under Wisconsin conditions indicate that soiling crops of good quality yield approximately a similar production of milk to corn silage. For the 3 years the cows fed silage produced 65,727 lbs. milk, 8,684 lbs. solids, and 2,737.2 lbs. milk fat, as compared with 65,922.7 lbs. milk, 8,644 lbs. solids, and 2,701.36 lbs. milk fat for the cows fed soiling crops. The expense of producing and feeding these soiling crops was considerably greater than that of producing and feeding silage.

"Years in which the rainfall is below normal, and the pastures therefore poor, are also the years when soiling crops are likely to be scant or fail. The carrying over of the corn crop from one year to the next by means of the silo tends to equalize the quantity of feed available from year to year; hence insures against losses in milk production due to a scarcity of feed."

The soiling crops used in these trials were red clover, peas and oats, early sweet corn, late sweet corn, and succotash, consisting of a mixture of oats,

peas, and dent corn. Of the green crops planted clover and succotash proved the least palatable. Suggestions are given for the feeding of cows in summer and for the use of the summer silo.

Analyses of the various feeds are appended.

[Studies on the fat, total solids, and dirt content of milk], H. FISCHER (*Die Ergebnisse der Kontrolle einer Genossenschaftsmolkerei, insbesondere Untersuchungen über den Fettgehalt, den Trockensubstanzgehalt, und die Verunreinigung der Milch. Inaug. Diss., Ludwigs-Univ. Giessen, 1912, pp. 67*).—In these studies the maximum milk yield was found to be in April and May, with a gradual decrease toward the fall and winter months. The daily variation of fat content ranged from 0.1 to 0.25 per cent. The fat content of the milk was low in April and June, reaching its first maximum in July and its second maximum in December. High fat content was associated with a high total solids content. The nature of the food showed a specific influence on the character of the milk, a ration high in fat content giving milk of high fat content. The frequency and manner of milking showed an influence on the composition of milk, the last part of the milking being the richest.

Constants for normal variation in the fat content of mixed milk, R. PEARL (*Maine Sta. Bul. 221 (1913), pp. 299-305*).—In this paper the author applies biometric methods to the experimental data compiled by Klose (*E. S. R., 30, p. 474*).

The results indicate that in general in the mixed milk of a large dairy herd the percentage content of fat is lowest in the morning milk and usually highest in the evening milk. Without exception the absolute amount of fat is greatest in the morning milk, least in the evening milk, and intermediate in amount at the midday milking, these amounts being dependent upon the length of interval between milkings. The difference between morning and evening milk in percentage of fat content is significantly smaller in March and October than in May and July. The percentage of fat content of the total day's milk rises steadily from March through October, approximately one-half per cent, the greater part of this increase occurring between July and October, and indicating that pasture conditions were a significant factor in producing the result. The greatest absolute mean fat production per day was in May with but slightly lower production in July and October.

The percentage fat content of the mixed milk of a large herd exhibits a considerable variation from day to day. It is most variable in March and October and least variable in May and July. The absolute amount of fat produced per day is roughly about twice as variable relatively as is the percentage fat content of the milk, indicating that the larger variation exists in the milk yield of the herd rather than in the percentage fat content of the milk. The relative variation in absolute fat produced decreases steadily from March to October although this decrease is small and not significant. The milk of any particular milking of the day is no more variable in percentage of fat content than the milk of any other milking of the day and the total day's milk is relatively less variable in fat percentage than the milk from any single milking. In absolute amount of fat the evening milk is relatively much more variable than the morning's milk, indicating that during the night fat production in the udder is a more uniform process than during the daytime when the cows are in some degree active.

Testing milk and cream for butter fat, O. F. HUNZIKER (*Indiana Sta. Circ. 42 (1914), pp. 22, figs. 29*).—This circular contains general information on methods of testing milk, cream, skim milk, and buttermilk by the Babcock test.

The origin of some of the streptococci found in milk, L. A. ROGERS and A. O. DAHLBERG (*U. S. Dept. Agr., Jour. Agr. Research, 1 (1914), No 6, pp. 491-*

511, figs. 8).—The authors summarize their observations as follows: "A collection of cultures of streptococci was made consisting of 42 cultures from milk which formed chains in lactose bile at 37° C., 51 cultures from infected udders, 114 cultures from bovine feces, and 39 cultures from the mouths of animals.

"The morphology varied under different conditions and could not be correlated with the source of the culture, except that the udder cultures had a more marked tendency to chain formation than those from other sources. The ability of these cultures to liquefy gelatin and to form acid from dextrose, lactose, saccharose, raffinose, starch, inulin, mannite, glycerin, dulcitol, and adonite was determined. Only one or two cultures utilized adonite or dulcitol. When glycerin was attacked, the fermentation proceeded slowly, failing to reach its maximum in 14 days, in contrast to the fermentation of the sugars, in which the maximum was reached in two or three days.

"A high percentage of the udder cultures failed to give the characteristic reduction in litmus milk. Twelve cultures liquefied gelatin; one of these came from milk and 11 from infected udders. The cultures from feces were characterized by their activity in fermenting the sugars, including raffinose, and their inability to utilize the alcohols. The mouth cultures fermented dextrose, saccharose, lactose, mannite, and frequently raffinose, but were almost without effect on starch and glycerin. The udder cultures were characterized by the general lack of fermentive ability, which was limited almost entirely to dextrose, saccharose, and lactose, with a comparatively small number utilizing mannite, glycerin, and gelatin.

"When the udder cultures were divided on the basis of gelatin liquefaction, two groups were obtained. The fermentive activities of one of these, which are similar to those of *Streptococcus pyogenes*, were limited to dextrose, saccharose, and lactose, with an occasional culture fermenting mannite, starch, or inulin. The second group fermented the 3 simple sugars, mannite, and usually glycerin and liquefied gelatin. When the milk cultures were considered individually, it was found that with the exception of two which clearly came from feces they could be included in one or the other of the two groups into which the udder cultures were divided. Of the 41 nonliquefying udder cultures 24 gave identical reactions. The remaining cultures differed from the type in one or two characters only."

Dirt sediment testing.—A factor in obtaining clean milk, M. C. SCHROEDER (*Amer. Jour. Pub. Health*, 4 (1914), No. 1, pp. 50-64, figs. 12).—After describing the various methods of making sediment tests, both of the gravity filtration and centrifugalization types, the author gives the results of tests made of 416 samples of milk to ascertain the factors influencing gravity filtration.

It was found that 11 per cent of the samples filtered through the cotton in less than one minute, 68.9 per cent in from 1 to 3 minutes, 7.4 per cent in from 3 to 5 minutes, 4.3 per cent in from 5 to 10 minutes, 4 per cent in from 10 to 60 minutes, and 4 per cent in over 60 minutes. The filtration process did not seem to be affected by the fat content, total solids, or the amount of sediment present in the form of visible dirt, but a large excess of leucocytes or epithelial cells tended to retard the filtration. Colostral and stripper milk filtered through quite readily. Sweet cream diluted with an equal amount of warm water may be tested, but in testing sour cream it is necessary to dissolve the curd by the addition of an alkaline solution. A gauge has been devised for making comparative readings which represent the amount of dirt obtained by filtering liter lots of milk to which have been added respectively 2½, 5, 7, and 10 mg. of the material which usually finds its way into the milk.

Minnesota dairy and food laws (*Minneapolis, Minn., 1913, pp. 104*).—This is a manual of the state dairy and food laws, and the rules and regulations relating to dairy inspection, preservatives of dairy products, pasteurization of milk and cream, labeling of butter and cheese, shipment of cream, sale of oleomargarine, and other related subjects.

The dairy industry in New York State (*N. Y. Dept. Agr. Bul. 54 (1913), pp. 447, pl. 1, figs. 103*).—This bulletin includes the text of the laws in force in New York relating to dairying, together with articles on the country milk situation in the State, handling and delivering city milk, bacteria in milk, sanitary economical appliances in clean milk production, the milking machine, and other related topics.

Distribution of moisture and salt in butter, E. S. GUTHRIE and H. E. ROSS (*New York Cornell Sta. Bul. 336 (1913), pp. 3-21*).—The purpose of this bulletin is to show the variation of moisture and salt in butter as found on the market. The samples used in this study came from churnings in different parts of the State of New York, which were immediately sent to market, and were in every way representative of the butter that is on the various markets. The analyses for moisture were all run in duplicate by the gravimetric method. The salt analyses were made by the silver nitrate method.

It is stated that "of the 51 packages 9, or 17.6 per cent, showed a difference of 1 per cent or more of moisture in adjacent samples, and in 11 packages, or 21.6 per cent, there was a difference of 1 per cent or more between the lowest and the highest moisture tests. Of the packages 54.9 per cent showed a difference of 0.5 per cent of moisture or over in adjacent samples. There was a difference of 0.5 per cent or more of moisture between the lowest and the highest moisture test in 60.8 per cent of the packages.

"In 36.2 per cent of the packages there was a difference of 0.2 per cent of salt in adjacent samples, and 46.8 per cent of the packages contained a difference of 0.2 per cent salt between the lowest and the highest tests. There were 4 instances of adjacent moisture tests being the same, and in 7 packages there were 2 or more samples that tested the same. In 12 packages adjacent salt tests were the same, and in 22 packages there were 2 or more samples that were the same in salt content. Poorly made butter varied slightly more in moisture and salt than did well-made butter."

It is concluded from these observations that "in order to get an approximate test of the moisture in butter, a sample containing only a few portions of butter may be used; but if the legal limit has been reached and the exact composition is wanted, the sample must consist of many portions taken from different parts of the package."

A study of some factors influencing the yield and the moisture content of Cheddar cheese, W. W. FISK (*New York Cornell Sta. Bul. 334 (1913), pp. 515-538*).—In a study made of the factors which influence the yield and the moisture content of Cheddar cheese it was found that "cutting the curd fine causes a larger loss of fat in the whey than cutting the curd coarse. Coarse-cut curd increases the yield of green and of cured cheese and increases the moisture content of the cheese. If great care is not taken and the pieces of curd are broken, the result will be the same as a fine cut.

"Setting the milk at a high temperature reduces the loss of fat in the whey more than setting the milk at a low temperature. Setting at a high temperature increases the yield of the green and the cured cheese. This increase is probably due to the increased moisture content of the cheese. A low acid at the time of removing the whey increases the yield of the green and the cured cheese. The low acid also increases the percentage of moisture in the cheese.

If a high acid is developed, it not only reduces the yield and the percentage of moisture in the cheese, but also injures the quality of the cheese.

"Stirring the curd with the hand as the last of the whey is removed reduces the percentage of moisture in the green and the cured cheese. Stirring reduces the yield and causes a larger loss of fat in the whey. Pressing the curd fast reduces the yield because more fat is squeezed out of the curd. This loss of fat makes the cheese pressed fast appear to contain more moisture. If the curds are piled deep more moisture is retained in the green and the cured cheese. Piling the curds deep increases the yield of cheese. An increase of salt in the curd results in the reduction of moisture in the cheese.

"Holding the curd at a low temperature after the whey is removed increases the percentage of moisture in the green and the cured cheese and increases the yield. An increase of rennet to a certain point increases the moisture content of cheese. This is due to greater coagulation, and has the same effect as setting at a high temperature or cutting the curd hard. Cutting the curd soft reduces the percentage of moisture and the yield of the green cheese, and also increases the loss of fat in the whey. Cutting soft has the same effect as setting at a low temperature or as a small amount of rennet."

A bibliography is appended.

The manufacture of cheeses in the Grisons from skimmed cow's milk and whole goat's milk, and the utilization of these milks in Germany, H. KRAEMER (*Mitt. Deut. Landw. Gesell.*, 28 (1913), Nos. 6, pp. 84-87; 7, pp. 103-105; 9, pp. 149-151; abs. in *Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, pp. 641, 642).—An account of a method of manufacturing skim milk cheese in Switzerland in which mixed cow's and goat's milk is employed. By this method the skimmed cow's milk is utilized to the best advantage, while the cheese product is materially improved by the addition of the whole goat's milk.

VETERINARY MEDICINE.

An introduction to the study of infection and immunity, C. E. SIMON (*Philadelphia and New York*, 1913, 2. ed., rev. and enl., pp. X+17-325, pls. 11, figs. 18).—This book, which is in its second edition, has chapters on serum therapy, vaccine therapy, chemotherapy, and serum diagnosis, and is meant for students and practitioners. It deals especially with infection in man.

Experimental production of agglutinins in animals by injecting salvarsan, J. NICOLAS, P. COURMONT, and GATÉ (*Compt. Rend. Soc. Biol. [Paris]*, 73 (1912), No. 28, pp. 245, 246; abs. in *Centbl. Bakt. [etc.]*, 1. Abt., Ref. 56 (1913), No. 7, p. 206).—In normal animals (dogs, and especially goats) a marked increase in the agglutination titer for tubercle bacilli and typhoid bacilli is produced as a result of injecting salvarsan. Agglutination is not increased in the guinea pig or rabbit.

Investigations in regard to the toxicity of fungi; their hemolytic power, J. PARISOT and VERNIER (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 14, pp. 620-623; abs. in *Chem. Ztg.*, 36 (1912), No. 151, p. 1472).—The hemolytic power of *Amanita phalloides* in vivo and vitro is very intense. It took less than 10 drops of an extract made from the fungus and injected intravenously to kill a young rabbit within a few seconds. Fungi which are not hemolytic while young acquire the hemolytic power when they grow older. Extracts not hemolytic at the outset will hemolyze after standing for 12 hours. Heating a hemolytic extract over an open fire for about 5 minutes destroys its hemolyzing power. The hemolyzing properties of this fungus probably depend to a great extent upon the presence of a glucosid.

Mode of union between the *Amanita hemolysin* and its antihemolysin, W. W. FORD and ETHEL M. ROCKWOOD (*Jour. Pharmacol. and Expt. Ther.*, 4 (1913), No. 3, pp. 235-239, figs. 2).—"If a fresh extract of *A. phalloides* be made, filtered through a Berkefeld filter, rendered isotonic by the addition of NaCl, the hemolytic strength of this solution can be determined with great exactness and correspondingly the exact quantity of the antihemolytic serum which will neutralize it, that is, produce a mixture which will have no solvent action on blood corpuscles. If now, increasing quantities of the hemolysin be employed and the amount of antihemolysin necessary for neutralization be determined, the increase in the antihemolysin can be found. By plating the data obtained by means of a system of abscissas and ordinates the manner in which the hemolysin and antihemolysin combine can be represented in a graphic way, and exact information obtained as to the law which holds for the union of the two. A similar series of observations starting with fixed quantities of antihemolysin and estimating the amount of hemolysin neutralized can also be made and in turn platted. We thus obtain 2 lines or curves showing the combining power of the hemolysin and antihemolysin."

The mode of union is of the simplest and follows the law of multiple proportions.

Note on the *Amanita* toxin, W. W. FORD and EDITH BRONSON (*Jour. Pharmacol. and Expt. Ther.*, 4 (1913), No. 3, pp. 241-243).—*Amanita* toxin was submitted to combustion analysis. For this purpose 200 gm. of the thoroughly dried fungus was extracted with alcohol and the poison was isolated by Schlesinger and Ford's method. "At every step in the procedure the various products were tested to determine their activity. The final solution had a high degree of toxicity, 1 cc. containing 0.0007 gm. of material killing a guinea pig weighing 175 gm. in 7 hours. This solution was then evaporated to dryness on a water bath, taken up in water and precipitated in absolute alcohol, in which reagent the purified toxin is practically insoluble. This last precipitate was dried in a vacuum desiccator.

"From the 200 gm. of fungus we obtained 0.2114 gm. of a slightly pigmented amorphous powder which represents the active principle and retained its toxicity unimpaired. This substance has failed to crystallize under any conditions which we have thus far been able to produce. Its amorphous character renders investigations into its chemical nature extremely difficult and the results of combustion analysis are necessarily of doubtful value."

The final product was of a high degree of toxicity. Its ash consisted of 9.5 per cent of sodium salts. The combustion analysis showed it to contain nitrogen and sulphur in large quantities and hydrogen and carbon.

"The hemolysin and the toxin differ radically, not only in their physiological properties but in their chemical reactions, and require different methods of preparation. The hemolysin, for instance, is precipitated by 65 per cent alcohol and by basic lead acetate, while the toxin is soluble in alcohol of this strength and is not thrown down by lead acetate. Many other chemical differences are to be noted. In spite, however, of the dissimilar methods of preparation the 2 final products, in both cases physiologically active, contain nitrogen and sulphur in addition to the elements carbon, hydrogen, and oxygen."

Action of extracts made from the mushroom (*Agaricus campestris*), boletus (*Boletus edulis*), and chanterelle (*Cantarellus cibarius*) upon the red blood corpuscles, E. FRIEDBERGER and G. A. BROSSA (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 15 (1912), No. 6, pp. 506-517).—This consists of an investigation in regard to the presence of agglutinins and hemolysins in the extracts of the above-named fungi. Toward the blood corpuscles of various animals, i. e., guinea pig, pig, rabbit, sheep, horse, and bovine, certain differences in

regard to the agglutination were noted. For instance, no agglutination was found with the bovine corpuscles and *A. campestris* extract, and the rabbit corpuscles were agglutinated the strongest.

Somewhat different was the behavior in the case of the *B. edulis* extracts, which agglutinated strongly at first, but was later followed by hemolysis of the cells. In some cases, after 2 hours hemolysis again set in. No agglutination was noted with the corpuscles of the guinea pig and sheep, and the greatest amount of agglutination was with rabbit corpuscles. The hemolysis was greatest with the horse corpuscles. Agglutination, in contrast to the results obtained with the mushroom, was present for bovine corpuscles.

With the chanterelle extracts no effect in regard to agglutination or hemolysis was noted with the corpuscles of the pig, horse, and sheep. Hemolysis was present only for guinea pig corpuscles. The hemolysin of *A. campestris* was found to withstand a temperature of 80° C. for 15 minutes, while a temperature of 95°, when exposed for the same length of time, completely destroyed the hemolysin. Heating the *B. edulis* extract for one-half hour at 60° preserved its agglutinating function but destroyed its hemolytic properties.

Horse and sheep sera were found to inhibit the action of a boletus extract upon homologous blood corpuscles. Rabbit serum had no inhibitory effect upon the agglutination. The strong inhibiting power of bovine blood serum is removed when, instead of the homologous blood, pig blood is used. On the other hand, pig serum acts more inhibitory toward bovine blood corpuscles than toward homologous blood corpuscles.

In order to determine whether the active principle present in the extracts is utilized during the agglutination process, tests were made with decreasing doses of mushroom extract and rabbit blood corpuscles, which were changed twice during the process. It was found that the agglutinating property for the rabbit corpuscles was entirely removed. The process is considered specific.

Note in regard to the precipitating serum for the protein of *Agaricus muscarius*, B. GALLI-VALERIO and M. BORNAND (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 17 (1913), No. 2, pp. 180-185).—Specific precipitins for the *A. muscarius* could be reproduced by immunizing rabbits with the protein (albumin) of the fungus. With it, it is possible to detect the presence of 1 part of *A. muscarius* in a mixture with 7 parts of *Boletus edulis*.

Among the fungi used for comparative purposes in the tests were *A. iridium*, *A. campestris*, *A. nudum*, *Cantarellus cibarius*, *B. edulis*, *Helianthus repandum*, *Morchella esculenta*, and *Tuber cibarium*.

This reaction may eventually be of great value in detecting the presence of poisonous fungi among edible mushrooms, and also for the purpose of detecting adulterations in these goods with inferior material.

Cicuta, or water hemlock, C. D. MARSH, A. B. CLAWSON, and H. MARSH (*U. S. Dept. Agr. Bul.* 69 (1914), pp. 27, pls. 4, fig. 1).—The plants of the genus *Cicuta* are of especial interest since they are probably the most violently toxic of all the plants growing in temperate regions. The poisonous principle is not in the aromatic oil which exudes when the rootstock is cut open but in a resin, this having been separated under the name cicutoxin.

The authors present a historical summary, a brief description of the genus *Cicuta*, distinguishing between *Cicuta* and *Conium*, and mention the popular names, localities where *Cicuta* poisoning has occurred, losses of live stock from *Cicuta* poisoning in the United States, and uses of *Cicuta*. Experimental work in Colorado, a report of which follows, is taken up under the headings of feeding experiments with sheep and with cattle in 1910 and experimental work in 1911. Under the heading of general conclusions are discussed the symptoms of *Cicuta* poisoning, autopsy findings, toxic dose, animals poisoned by *Cicuta*,

water poisoned by *Cicuta* roots, the part of the plant which is poisonous, season when most poisonous, and remedies for *Cicuta* poisoning.

It is shown that the poisonous properties of *Cicuta* have been recognized since the middle of the seventeenth century and that a large number of cases of poisoning of man and animals have been reported. The toxic principle is probably common to all species and there is reason to think that all species are equally poisonous. There is a definite train of symptoms, marked by nausea, pain, and violent convulsions, which makes it easy to diagnose cases of *Cicuta* poisoning. The prominent lesions, as found in autopsies, are congestion of the lungs, kidneys, and central nervous system, with inflammation of the alimentary canal. So far as known all the higher animals are poisoned by *Cicuta*. The quantity necessary to poison is very variable, depending probably on the stage of growth, although the plant is very poisonous at all times. The toxic principle is largely confined to the rootstock. The tops under ordinary circumstances are not poisonous and neither the tops nor seeds when found in hay are a source of danger. An emetic is said to be the best remedy, there being very little that can be done for poisoned live stock.

A bibliography of the literature cited, consisting of 51 titles, is appended.

The influence of the subcutaneous mallein test upon the diagnostic blood examination in glanders, *Ä. MARCIS* (*Berlin. Tierärztl. Wchenschr.*, 29 (1913), No. 35, pp. 621-624, figs. 2).—After the subcutaneous administration of mallein there are produced in the blood of nonglandered animals specific precipitins, agglutinins, and complement-fixing amboceptors. These are the same as occur in glandered horses. The precipitins are present the third day after the injection. The agglutinins come after 5 to 7 days, and the complement-fixing amboceptors 6 to 10 days post injection. The various antibodies disappear in the same order. Most of the antibodies present in animals treated with mallein begin to disappear the second or third week after the mallein injection, and after 3 months they are totally absent; consequently 3 months must elapse after the mallein injection before correct results can be obtained with the blood tests.

The effect of cold upon the larvæ of *Trichinella spiralis*, *B. H. RANSOM* (*Science*, n. ser., 39 (1914), No. 996, pp. 181-183).—The author reports the results of a single series of experiments which show that cold has a lethal action upon *Trichinella* larvæ. In the experimental work most of the parasites survived when exposed for 6 days to a temperature ranging between 11 and 15° F., but when exposed to a temperature of about 0° F. the larvæ quickly succumbed, only one of more than 1,000 larvæ examined having survived the 6 days' exposure to this temperature. The single trichina which survived was one of 275 isolated from a piece of trichinous meat which had been kept at a temperature of about 0° F. from September 27 to 30, then allowed to thaw, and again kept at the same low temperature from October 1 to 4, or a total of 6 days' exposure. "None was found alive among 498 larvæ from a piece of trichinous meat kept at about 0° F. September 27 to 30, allowed to thaw, then exposed again to the same low temperature October 1 to 3, and thus exposed 5 days in all, nor was any found alive among 233 larvæ from a piece of trichinous meat kept continuously at about 0° F. for 5 days. Out of 301 larvæ from trichinous meat kept at about 0° F. for 3 days only 5 showed signs of life. Two hundred and twenty-five out of 366 larvæ exposed for 2 days to a temperature of about 0° F. were dead, and many of the remaining 141 showed only faint signs of life. Results similar to the above were obtained from tests of trichinosed meat on guinea pigs."

The results of these experiments suggest the possibility of substituting refrigeration for microscopic inspection as a prophylactic measure.

Trypanosoma americanum, F. M. JOHNS (*New Orleans Med. and Surg. Jour.*, 66 (1914), No. 7, pp. 533, 534; *abs. in Amer. Jour. Trop. Diseases and Prev. Med.*, 1 (1914), No. 8, p. 594).—This paper reports upon a biological study made of this nonpathogenic parasite of cattle.

Contribution to a study in regard to the relation of human tuberculosis to bovine tuberculosis, D. G. IZCABA (*Off. Internat. Hyg. Pub. [Paris], Bul. Mens.*, 5 (1913), No. 8, pp. 1337-1343).—Following a review of the literature in regard to the relation of bovine tuberculosis to tuberculosis in man, some feeding tests with guinea pigs are reported. In some instances the animals received the meat of tubercular animals and in other cases the meat juice.

Only the meat of animals affected with miliary or acute generalized tuberculosis produced tuberculosis in the guinea pigs; localized cases did not. The statistics relating to the occurrence of bovine and human tuberculosis in Spain are discussed.

Guinea pigs were also fed raw milk obtained from the open market. The six which received the milk as purchased remained sound, while the six which were given the lower portion of the centrifuged milk became tuberculous. In another group of guinea pigs in which the milks were administered by the intraperitoneal route, only two of the six receiving the milk as purchased became tuberculous, whereas of the six which received the lower portion of the centrifuged milk four became tuberculous. A third group of animals received hypodermic injections of the milks. Only one of the six receiving the milk as purchased became tubercular, whereas two out of the six given the lower centrifuged portion became diseased. The statistics in Spain relating to the causation of tuberculosis by the consumption of milk from tuberculous cows are also discussed.

About atypical tuberculosis in slaughtered animals, HAFEMANN and BINDER (*Ztschr. Fleisch u. Milchhyg.*, 23 (1912), No. 6, pp. 124-131, figs. 2; 23 (1913), No. 7, pp. 153-156, fig. 1; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 20, p. 620).—Tests made with 4 calves, 1 adult bovine, and a pig brought out the fact that in the lymphatic glands undergoing rayed caseation, as first described by Bongert, tubercle bacilli are often present. In the lymphatic glands accompanying this rayed caseation there occur peculiar, macroscopically visible changes which are seldom observed in tuberculous pigs. The changes are observed most often in the periphery of the cell, but also appear on the walls of the gland in the cut preparation, or they may appear a little inwardly as a light gray wreath containing small punctate bodies. When such lymph glands are observed, the presence of tuberculosis is rarely suspected by the inspector, but it is not a difficult matter to detect the tubercle bacilli in these glands with the antiformin method. This atypical form of tuberculosis has some characteristics which are similar to those atypical cases which have been described in man by Liebermeister.

[About atypical tuberculosis in slaughtered animals], HAFEMANN and BINDER (*Ztschr. Fleisch u. Milchhyg.*, 23 (1913), No. 23, pp. 531, 532).—A continuation of the work noted above. It is pointed out that the pathologic condition is noted but seldom in the lymphatic glands of the cow's udder. The histological findings showed a connective tissue proliferation. Investigations were conducted for the purpose of determining the cause of this connective tissue proliferation. In the literature of human medicine similar findings are recorded.

The authors noted the presence of tubercle bacilli in seven cases and the conclusion is reached that the process is of a tuberculous nature. It is, however, pointed out that virulent tubercle bacilli are seldom present in the lymphatic glands of either pigs or cows which show the pathologic changes under discussion.

The intradermal test for tuberculosis in cattle and hogs, C. M. HARING and R. M. BELL (*California Sta. Bul.* 243 (1914), pp. 93-154, figs. 20).—Some of the material reported in this bulletin has been noted from another source (E. S. R., 29, p. 499). "In all, 4,926 intradermal tests have been made on 4,001 cattle, 1,614 of which reacted, and there has been an opportunity to check these results by autopsies in 341 cases and by the discovery of lesions on physical examination in 54 additional cases. To 291 cattle that reacted to the intradermal test the subcutaneous test was subsequently or simultaneously applied, and 282 cattle reacted. Forty-four cattle with a positive intradermal reaction gave no thermal reaction to the subcutaneous test."

It was possible to bring to autopsy only 10 of the cattle which failed to react to the subcutaneous method, but in 9 of these tuberculous lesions were noted. Thirty-five of the cattle which failed to react to the intradermal test later reacted to the subcutaneous test. "Two of these cows which reacted to the subcutaneous method, but showed no swelling at the point of intradermal injection, were found on autopsy to be tuberculous."

The cattle which reacted to the intradermal test and manifested a local swelling usually showed a thermal reaction which resembled that produced by the ordinary subcutaneous injection. When an intradermal injection was given a few days after a subcutaneous injection, the results obtained were not reliable. "The thermal reaction which accompanies the intradermal injection usually subsides in 20 hours, but it seems desirable not to apply the subcutaneous test for several days after the intradermal. The longer the interval the better."

While the results with Koch's tuberculin in 10 per cent solutions and with alcoholic precipitated tuberculin in 0.5 per cent solutions compared favorably in accuracy with the usual subcutaneous method, a more satisfactory method seemed to be to give one-fifth cc. of a 5 to 50 per cent solution of an alcoholic precipitated tuberculin in the subcaudal fold and to administer 2 cc. of Koch's old tuberculin (10 per cent) subcutaneously. "With this kind and strength of tuberculin the local reactions are pronounced and the thermal reactions are as characteristic as those that occur from subcutaneous injections alone."

The application of strong disinfectants at the site of injection is to be avoided.

The intradermal reaction is much harder to interpret than either the ophthalmic or the subcutaneous test inasmuch as a great deal of experience is necessary to interpret the significance of the local swelling. This is especially true when glycerin is present in the tuberculin. "When 5 per cent solutions of potent precipitated tuberculin are used both the ophthalmic and intradermal methods equal the subcutaneous test in accuracy, but we have found that the ophthalmic method is unsuitable for use in routine testing under California conditions, except when the cattle can be kept indoors. The intradermal method has proved very satisfactory in the out-of-door tuberculin testing frequently necessary in this State, and for the nonofficial testing of large numbers of cattle is preferable to the subcutaneous method. . . . By administering the ophthalmic, intradermal, and subcutaneous tests simultaneously, a higher percentage of tuberculous cattle will be detected than if dependence is placed on one test alone.

The intradermal test was also found very valuable for detecting tuberculosis in hogs. A dose of one-fifth cc. of 10 per cent precipitated tuberculin was used and with it tuberculous hogs often showed a thermal as well as a local reaction. No decision was reached as to the best site for making the injection. The larger swellings, however, were noted when the injection was made at the edge of the ear. For measuring the swelling a special form of caliper is described and illustrated.

The bulletin is well illustrated with cuts showing the method of applying the test and the results obtained after giving tuberculin. The protocols of autopsies and the work of other authors are included, with a bibliography of 57 titles.

Texas or tick fever, J. R. MOHLER (*U. S. Dept. Agr., Farmers' Bul. 569* (1914), pp. 24, figs. 5).—This is a revision of and supersedes Farmers' Bulletin 258, previously noted (*E. S. R.*, 18, p. 181).

Actinomycosis of the mammary gland in dairy herds in Victoria, E. A. KENDALL (*Vet. Jour.*, 70 (1914), No. 465, pp. 132-148).—A paper read before the Australasian Association for the Advancement of Science, at Melbourne.

A bovine disease caused by the *Bacillus necrophorus*, M. BALOGH (*Állatorrosi Lapok*, 36 (1913), No. 35, pp. 415-417; *abs. in Vet. Rec.*, 26 (1914), No. 1333, p. 470).—*B. necrophorus* was found present in the ulcers of an affection, observed for several years in cattle in Hungary, which had hitherto been regarded as an atypical form of bovine malignant catarrhal fever.

Care of the teeth in dairy cattle, D. CULLEN (*Breeder's Gaz.*, 65 (1914), No. 1684, p. 522).—The author reports that on examination of 500 cows he found diseased or irregular teeth in 371, or over 60 per cent; of these 47 had one or more teeth diseased, 19 had one or more teeth absent, and 31 had one or more points of enamel protruding through the mucous membrane of the cheeks.

Strongylus capillaris of the camel, A. PRICOLO (*Centbl. Bakt. [etc.]*, 1. Abt., *Orig.*, 71 (1913), No. 2-3, pp. 201, 202).—*S. capillaris*, here described as new, is a habitual parasite in the small intestine of dromedaries in Tripoli, often being associated with hemorrhage, hyperemia, and catarrh of the intestinal mucosa.

A study of epithelioma contagiosum of the common fowl, C. D. SWEET (*Univ. Cal. Pubs., Zool.*, 11 (1913), No. 3, pp. 29-51).—"Epithelioma contagiosum is a specific infectious disease. The virus is constantly present in material from the lesions found on the head and on the buccal mucous membranes, and in the blood of infected fowls. The disease is readily and constantly produced by inoculation with material from the lesion or with the blood from infected fowls. This inoculation is not the transplantation of tumor cells from one fowl to another, as the virus is present in the filtrate after passage through a Berkefeld filter, and so far as we are able to discover neoplasms have not been produced by inoculation with such filtered extract, with the exception in one case of a sarcoma of the fowl transmissible by an agent separable from the tumor cells as described by Rous (1911) [*E. S. R.*, 25, p. 90].

"The period of incubation varies from 3 to 12 days, depending on the virulence of the virus and on the method of inoculation. The virulence of the virus is lowered by age and by the action of chemicals. Within limits the virulence of the virus increases with passage through a fowl. An immunity is produced, which is complete within a definite time, is specific, and of considerable duration. The tissue reaction at the point of inoculation is very similar to that produced by inoculation with known infectious agents. There is a definite relation between the resistance of the host and the virulence of the infection, i. e., an inoculation with a virus of reduced virulence produces a reaction that is entirely local, while a more virulent strain produces a reaction that is not limited to the point of ingress. In response to an inoculation with epithelioma contagiosum there is produced a specific antibody in the blood of the host.

"Epithelioma contagiosum and roup are entirely independent diseases. Epithelioma contagiosum is constantly and readily transmitted by inoculation, while roup is not (Ward). Immunity conferred by an inoculation with the

virus of epithelioma contagiosum does not prevent the contraction of roup. Under the conditions of our experiment, epithelioma contagiosum was not fatal to mature fowls, while all that contracted roup died. The cell inclusions present in the hyperplastic epithelial cells of epithelioma contagiosum show changes which may perhaps represent stages in the development of a protozoan parasite, but we are unable so to connect them that a complete life cycle is definitely established."

A bibliography of 26 titles is appended.

RURAL ENGINEERING.

Frictional resistance in artificial waterways, V. M. CONE, R. E. TRIMBLE, and P. S. JONES (*Colorado Sta. Bul. 194 (1914), pp. 48, figs. 41*).—A series of field experiments in cooperation with this Office with metallic, reinforced concrete, and timber flumes, concrete lined and earth canals, concrete and timber chutes, and inverted siphons of wood-stave pipe are reported which were conducted to determine (1) the coefficient of roughness in empirical formulas for the several types of open channels; (2) whether such coefficient changes with variations of discharge; and (3) the loss of head in water flowing through siphons, to compare Kutter's formula with the ordinary friction formula as adapted to pressure pipes, and to compare the accuracy of different methods of making current meter measurements.

The average values found for the coefficient of friction n in Kutter's formula for the several types of open channel were as follows: (1) Semicircular metallic flumes, smooth water face, wasteways less than 100 ft. long, 0.021; smooth water face, 0.011; joint connections protruding into the waterway, 0.0174; corrugations at right angles to the line of flow, 0.0225. (2) Timber flumes, lined with patent roofing material, 0.016; planed lumber, battens on the sides, flooring placed transversely, 0.015; planed lumber, battens on the sides, flooring placed longitudinally, 0.012; planed lumber, no battens, perfect alignment, 0.011. (3) Concrete-lined channels, smooth concrete or mortar-finished surface, 0.012; surface unplastered as left by forms, 0.016; bed exceptionally smooth, fine silt, uniform cross-section, straight alignment, 0.017; bed of hard, water-worn adobe, 0.022; bed of coarse gravel and small loose stones, 0.024; banks, smooth clay; bottom, fine sand; grass hanging into water, 0.027; bed, hard, water-worn adobe, many fine roots projecting, 0.028; bed, fine silt, merging into clay, many large, loose stones, 0.030; bed, little gravel, mainly smooth, rounded stones, 0.032.

The following table gives the hydraulic elements as found for wood-stave siphons:

Hydraulic elements of wood-stave siphons.

Diameter.	Length of pipe	Maximum pressure head.	Discharge.	Mean velocity.	Total loss of head.	(c) ¹	(n) ²	(f) ³
<i>In.</i>	<i>Feet.</i>	<i>Feet.</i>	<i>Second-feet.</i>	<i>Ft. per sec.</i>	<i>Feet.</i>			
48.....	486	51	20.34	1.62	0.497	49.4	0.0271	0.1005
48.....	515	66	20.44	1.63	.202	82.2	.0172	.0380
36.....	815	15.25	2.16	.515	98.6	.0140	.0262
60.....	363	37	49.70	2.53	.669	52.8	.0275	.0925
60.....	1,621	99	49.70	2.53	1.045	89.7	.0169	.0324

54.....	544	83	52.68	3.31	.942	75.0	.0195	.0458
54.....	2,563	60	53.99	3.39	2.205	109.1	.0139	.0220
54.....	803	77	53.99	3.39	1.438	75.6	.0193	.0449

¹ Value of (c) in Chezy formula $V=c\sqrt{rs}$.

² Value of (n) in Kutter's formula.

³ Value of (f) in formula for lost head due to friction and curvature, $h=f\frac{L}{d}\frac{V^2}{2g}$

Discharges varied in the inverse ratio as the coefficient of roughness, the hydraulic radius and slope remaining constant.

The vertical velocity curves for the timber flumes are flatter than those for the earth sections and approach more nearly a vertical position. "In general . . . the amount of distortion of the vertical curves from a vertical line varies directly as the roughness of the bed."

It is concluded as regards current meter measurements: (1) The multiple point method gives the closest determination of the actual mean velocity and should be used where accuracy is more essential than time, and where the conditions of flow are constant. (2) The vertical integration method is applicable where reasonable accuracy is desired in a comparatively short time. (3) The 0.2 and 0.8 method is more rapid than either of the previous ones, but should not be used in very narrow or very shallow channels. (4) Actual experience has shown that the assumption upon which the 0.6 method is based is not true in all cases. "With either the 0.2 and 0.8 or the 0.6 method approximate results will probably be obtained, the degree of accuracy varying with the cross-sectional factor and the roughness of the material."

A comparison of formulas for estimating run-off, J. W. CUNNINGHAM (*Engin. and Contract.*, 40 (1913), No. 25, pp. 690, 691, fig. 1).—For the purpose of comparison the author gives the algebraic statements of a number of formulas for run-off, with results platted from conditions existing in southern Wisconsin. The extreme variation in results leads to the conclusion that the use of formulas for run-off is dangerous, unless such formulas are well founded on a thorough study of local data and conditions.

Irrigation experiments at the experimental farm of the Royal Imperial College of Agriculture at Gross Enzersdorf (Austria) (*Zentbl. Landw.*, 93 (1913), No. 9, pp. 101-112; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1191, 1192).—Three years' flooding-irrigation experiments were conducted on 247 acres of a 10-acre field of 4-year-old alfalfa. The irrigation water was supplied by centrifugal pumps from underground sources. The test plat was divided into 10 plats, 1 remaining un-irrigated, 3 receiving about 148,000 cu. ft. of water, 3 others receiving 258,000 cu. ft. of water during the vegetative period, and the last 3 being irrigated only in the autumn. All the plats were manured alike.

On the unirrigated plat a close relation was found between temperature and the time of harvest, and also between the rainfall and the amount of crop. This plat yielded 3 crops with 28 cwt. of dry substance per acre. Only the first crop was satisfactory, the others being poor and unreliable. Four crops were obtained from the irrigated plats, the average results being as follows: Plats irrigated during the vegetative period with 148,000 cu. ft. of water produced 4 tons, those with 258,000 cu. ft. 3 tons, and those which were irrigated only in the autumn $3\frac{1}{2}$ tons of dry matter per acre.

Irrigation experiments with brackish water, O. BORDIGA (*Abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1192-1194).—To determine the possibility of utilizing brackish water for irrigation on a large scale a series of pot experiments was conducted using water of different degrees of salinity. Detailed analyses of the soil show that it was clayey and had good mechanical structure and chemical composition.

In the experiments, cotton, chicory, maize, and tomatoes were planted in zinc vessels, each containing from 180 to 185 lbs. of soil, and manured by the addition of 12 gm. of bicalcic phosphate and the same amount of ammonium sulphate. The cotton and chicory died, but the other two crops were each watered with different solutions as follows: Pure water; water containing 0.7389 per cent of salts as chlorids and carbonates; and water containing $\frac{1}{4}$, $\frac{1}{2}$,

and $\frac{3}{4}$ of this amount of salts. The plants were watered when they appeared to need it, and received every time sufficient to form a stratum from 1.2 to 3.6 cm. deep, the total amount received being 36.6 cm. by the maize, and 33.6 cm. by the tomatoes.

During the vegetative period the maize appeared to suffer from the salts, especially when they were present in the larger quantities, while the tomatoes seemed in no wise affected. The yield of maize decreased with an increase of salts. In the case of the tomatoes, the maximum weight of plant was obtained with the least salt, but the weight of fruit obtained with the maximum amount of salt was greater than that obtained with the smaller doses, though smaller than when fresh water alone was used. It is noted that maize irrigated with fresh water yielded within 4 months at the rate of 50 cwt. of dry matter per acre, and when irrigated with brackish water the yield was a little less than half. Tomatoes with fresh water yielded at the rate of 18.3 cwt. of dried stems and leaves per acre and 121 cwt. of fruit per acre, while with brackish water the weight of the dried stems and leaves was 20.3 cwt. and that of the fruit 111.5 cwt.

Federal v. private irrigation, D. C. HENNY (*Engin. News*, 71 (1914), No. 3, pp. 120-124).—From a comparison between the cost of private and government irrigation, and an analysis of factors affecting this, the conclusion is drawn that the cost of irrigation is far more dependent upon local conditions than upon the agency through which it is effected. The author presents and compares results as to settlement, points out the need of public funds for future irrigation development, discusses various features of the Reclamation Act, and indicates changes in the law which he thinks are desirable.

State rivers and water supply commission (*Victoria Rivers and Water Supply Com. Ann. Rpt.*, 8 (1913), pp. 37).—This is a report and statement for the financial year 1912-13 regarding the water supply, irrigation, drainage, water measurement, and flood protection. Marked progress in the extent and practice of irrigation is noted.

Measuring devices [irrigation], B. A. ETCHEVERRY (*Jour. Electricity*, 31 (1913), Nos. 3, pp. 68-70, fig. 1; 4, pp. 90, 91, fig. 1).—This article describes the use of rating flumes, weirs, a weir box and take-out from pipe line under pressure, a miners' inch board or box, and submerged orifices for the measurement of irrigation water.

Pumping and other machinery, A. A. MUSTO (*Dept. Agr. Bombay Leaflet* 8 (1912), pp. 19, pl. 1, fig. 1).—This pamphlet presents the main features to be considered in developing pumping projects, and describes the procedure usually followed by the agricultural engineers of the department.

Designing water conduits of large diameter, A. C. JANNI (*Engin. News*, 71 (1914), No. 2, pp. 66-68, figs. 6).—It is stated that "in a horizontal pipe containing water the internal pressure is much less at the top than at the bottom, and the stresses in a circular element are not purely tensile, but comprise a tension and a bending moment" which in large pipes or conduits becomes determinative. On this basis the author analyzes the design of large water conduits, giving formulas for covered conduits based on Guidi's method, and computing moment diagrams for a covered conduit on two assumptions as to vertical reaction and a stress diagram for bottom sections.

A bibliography of foreign works on the subject is appended.

Farm drainage, C. F. BROWN (*Utah Sta. Bul.* 123 (1913), pp. 5-56, figs. 14).—This bulletin is intended as a practical treatise, supplementing the series of co-operative investigations and practical field demonstrations between the Utah Station and the Drainage Investigations of this Office. It emphasizes the

general need for drainage in arid regions with reference to seepage and alkali problems, and is intended to cover "all engineering phases of farm drainage from the general observations concerning specific needs of drainage to the realizations of successful reclamation."

The road problem, J. H. A. MACDONALD (*Rpt. Brit. Assoc. Adv. Sci., 1912, pp. 373-383*).—The author discusses the past, present, and future of road construction, particularly pointing out the marked disadvantages resulting from road rolling, such as the formation of transverse ridges and furrows, the formation of potholes where road metal is mixed with mud and rolled, and the tendency to use too large stones. He draws attention to the enormous increase in motor traffic and concludes that present and future construction, particularly of the road crust, must in consequence be adapted to the traffic.

Mechanical engineering aspects of road construction, R. E. CROMPTON (*Surveyor, 45 (1914), No. 1146, pp. 4-10, figs. 6*).—The opinion is expressed that the development of road locomotion must be jointly studied by vehicle designers and road engineers. A brief review of the development of self-propelled vehicles and a description of the waving of road crusts and the conditions which cause and accentuate them are followed by the author's views as to the methods of road crust construction to prevent or minimize such action. It is pointed out that there is a great tendency for modern motor vehicles of the heavier classes to have nearly the same percussive and rebounding effects, and that the frequent passage of such traffic along a road tends to produce a regular wave formation of equal wave lengths. Initial waving is said to be produced in the process of rolling, and the use of a special three-axle roller is advocated.

In conclusion it is shown in tabular form the extent to which the present running costs of vehicles may be reduced by a well considered reconstruction of road surfaces.

Construction of bitumen bound broken stone roads, J. W. SMITH (*Good Roads, n. ser., 6 (1913), No. 10, pp. 99-110*).—In a paper before the Third International Road Congress, London, it is concluded that by the use of tarry, bituminous, or asphaltic binders a number of different forms of road crust may be obtained which may be employed with advantage according to the various conditions of the road as regards traffic, locality, and climate. For this purpose it is suggested that a uniform system of tests, measurements, and records be drawn up, including physical and local conditions, materials employed, method of construction, traffic census, climatic conditions, periodical measurement of wear, and actual cost of the road crust as regards construction and maintenance. Other related subjects are discussed in detail.

Agricultural surveying laboratory manual, D. SCOATES (*Agricultural College, Miss., 1913, pp. 33*).—This manual, intended for the student of agricultural surveying, deals with the principal basic problems of the subject, giving assignments with instructions as to procedure, noting the necessary equipment, and including a set of sample notes for each problem.

Variations in results of sieving with standard cement sieves, R. J. WIG and J. C. PEARSON (*U. S. Dept. Com., Bur. Standards Technol. Paper 29 (1913), pp. 16, fig. 1*).—A number of tests to determine what order of discrepancy may be expected in fineness determinations of cement by the standard routine method of sieving included investigations on differences in the standard sieves, the so-called "personal equation" of the observer, lack of uniformity in samples, and residual errors.

It is concluded that both sieving tests and the interpretation of measurements on sieves are subject to considerable discrepancies, that errors due to "personal equation" are appreciable in hand sieving, and that the rating of a sieve by

some system of demerits assigned from direct measurements is worthy of further study.

"The sieve at best is a measure of the coarseness of finely ground material rather than the fineness, and experiments now in progress . . . indicate that air separation will offer a more satisfactory means of determining fineness than mechanical sieving." It is further concluded that a tolerance of 1 per cent from the specification should be allowed with the No. 200 sieve and 0.5 per cent with the No. 100 sieve, every care being taken to conduct the test in strict accordance with standard methods.

French tests on oil-mixed concrete, R. FERET (*Ann. Ponts et Chaussées*, 9. ser., 17 (1913), pt. 1, No. 5, pp. 413-436, pl. 1; *abs. in Engin. News*, 70 (1913), No. 25, pp. 1228, 1229).—A series of French tests on the effect of mixing a heavy mineral oil with a concrete on the density and water repelling qualities leads to the conclusion that it is much simpler and cheaper to obtain a maximum density of mortar by a judicious choice of sand and by carefully proportioning the mix than by the addition of a water-proofing agent.

Effect of hydrated lime on Portland-cement mortars, H. S. SPACKMAN (*Engin. Rec.*, 69 (1914), No. 1, pp. 25, 26, figs. 9).—Investigations of the effect on the physical characteristics of the hardened mortar of the addition of hydrated lime to Portland cement to increase the plasticity and impermeability are reported with curves of results.

It is concluded from these tests that the addition of hydrated lime to cement mortars is to be recommended on the grounds that, in addition to making the mortar more plastic and impermeable, its use will probably result in a reduction in tendency of the mortars to shrink and crack, greater durability, and probably an increase in strength beyond that needed in the laboratory tests, as the greater plasticity will permit of better work being done by artisans.

Cement pipes and distributing stand pipes, B. A. ETCHEVERRY (*Jour. Electricity*, 31 (1913), No. 10, pp. 216-219, figs. 7).—This article describes and illustrates the underground cement pipe system of water distribution, particularly for orchard irrigation. Information is given regarding the location and construction of the system, particularly discussing the construction and operation of the stand pipes containing the regulating valves.

Some data on reinforcing concrete pipe, C. E. SIMS (*Concrete-Cement Age*, 3 (1913), No. 5, pp. 204, 205).—Tests of the relative value of different methods of reinforcing concrete drain tile showed that single-hoop reinforcement at the wall center and longitudinal reinforcement added little to the strength of the tile. The best results were obtained with double-hoop reinforcement.

The use of the formula $M=0.075 WD$, developed in connection with the tests for computing reinforcement, is illustrated. M equals the negative bending moment at the crown, W is the weight in pounds per inch in length of tile, and D is the diameter of the tile from the wall centers.

Transverse strength of screws in wood, A. KOLBERK and M. BIRNBAUM (*Cornell Civ. Engin.*, 22 (1913), No. 2, pp. 31-41, figs. 4; *abs. in Engin. and Contract.*, 40 (1913), No. 25, pp. 694-696, figs. 4).—The results of tests to determine the strength of ordinary cut screws in single shear in cypress, yellow pine, and oak joints are reported, and the following conclusions are drawn:

In cypress, the effect of boring holes for the screws is to weaken slightly the joints, while the opposite is true in yellow pine. Friction between adjoining pieces plays only a small part in the strength of the joint. Decreasing the number of screws per joint increases slightly the strength per screw. To secure the best results in a wooden joint, the outer piece should be about 0.4 the length of screw. For a particular gage, equal penetration into the middle piece

will give equal transverse strength, regardless of the thickness of the side piece, provided it supplies sufficient bearing area. The transverse strength per screw in yellow pine or oak varies directly as the square root of the penetration into the middle piece, while in cypress it varies directly as the cube root of the penetration in the middle piece.

For a particular length of screw the smaller the gage the greater the strength per pound of screws. As the length of screw is increased the strength per pound is decreased, the gage remaining constant. As the number of screws per pound is increased the strength per pound is increased, irrespective of length or gage; the strength of a yellow pine joint is about 80 per cent, and of a cypress joint about 40 per cent of that of an oak joint. There is no apparent simple relation between gage or diameter and transverse strength. The smaller the gage the more economical the screw, the length remaining constant. The gage remaining constant, the shortest screws will be most economical.

Sun-power plant (*Sci. Amer. Sup.*, 77 (1914), No. 1985, p. 37, figs. 2).—A comparative estimate of the cost of power from coal and from solar radiation "shows that the sun-power steam generator will compete in the tropics with a coal-burning steam generating plant which can obtain its coal at a rate of only \$2.40 per ton delivered to the furnace doors. Any excess in the cost of coal burning beyond this figure is clear profit in favor of the sun-power plant."

Utilizing waste heat of a small gas engine (*Power*, 38 (1913), No. 27, pp. 922, 923, figs. 3).—This article describes and diagrammatically illustrates the utilization of the heat carried off in the exhaust and jacket water from an 8-horsepower gas engine. The exhaust heat is utilized in a drying closet, and the velocity of the exhausting gas as an exhauster for dust and dirt. The jacket-water heat supplies hot water and hot chemical mixtures.

An experimental study in multiple effect evaporation, N. DEERB (*Hawaiian Sugar Planters' Sta., Agr. and Chem. Bul.* 42 (1914), pp. 47, figs. 9).—This bulletin describes methods employed and reports results of three years of experimental work in a number of mills with multiple effect evaporation under continually reduced pressure. The experimental work included investigations on such subjects as rate evaporation as influenced by the vacuum in the last cell, by higher initial temperature, and by variation of the temperature of the steam entering a cell of an evaporator and the temperature in the vapor space; heat economy of evaporators; and the evaporative capacity of quadruple-effect vertical submerged tube and horizontal tube apparatus. General results and conclusions are as follows:

"The temperature difference in the first cell is a rough index of the rate of evaporation.

"The vapors in a multiple effect evaporator are superheated.

"The calculated effect of self-evaporation in a multiple effect evaporator is never realized, due to superheating of vapors and to short-circuiting of vapors with the incondensable gases.

"Not only is the rate of evaporation influenced by the gross temperature difference, but it is also affected by the absolute temperature prevailing, increasing as this increases.

"Increase of the gross temperature difference by means of decreasing the temperature at the cold end up to the temperature corresponding to a vacuum of 27 in. gives a material and valuable increase in the rate of evaporation, but this increase is not by any means as great as is obtained by a similar increase in gross temperature difference obtained at the hot end by increasing the temperature (or pressure) of the steam.

"The heat economy of quadruple effect evaporators as found in practice compared with a computation on ideal lines lay between 0.8 and 0.9. This latter figure was found with well protected and the former with unprotected or badly protected apparatus.

"A vertical submerged tube apparatus with 5 lbs. gage pressure in cell 1 (227° F.) and not less than 26.5-in. vacuum in last cell (127° F.) should evaporate not less than 9 lbs. water per square foot per hour, with juice entering at 212° F. and should evaporate 4.2 lbs. water per pound of steam. If these conditions are not realized foul heating surfaces, too slow evacuation of condensed waters or incondensable gases, may be looked for.

"A horizontal tube film evaporator had a much greater rate of evaporation than vertical submerged tube evaporators."

The heat balance of a cane-sugar factory, N. DEERR (*Hawaiian Sugar Planters' Sta., Agr. and Chem. Bul. 43 (1914), pp. 21*).—Investigations on the heat value of bagasse and the steam generated by its combustion, the steam required in evaporation in single and multiple effect, and the heat represented by work, are reported. The mean heating value of bagasse is taken as 8,100 B. T. U. per pound of dry bagasse, and the actual heat of combustion is taken as the basis of calculation of the efficiency of bagasse as a fuel.

Comparative tests of a water tube boiler and smoke tube tandem boilers showed that on the average the smoke tube boilers evaporated 2,815, and the water tube boilers 2,328 lbs. of water per pound of bagasse from and at 212° F. "This gives a superiority in so far as regards steam per pound of fuel of 20 per cent; this increased economy is to be attributed solely to the much greater proportion of heating surface per pound of fuel burnt. . . .

"The efficiency of combustion as evidenced by the percentage of CO₂ in the flue gases is very much the same and the superiority in economy found with the tandem boiler is simply due to the greater reduction in the temperature of the products of combustion due to the larger heating surface."

A comparison of the relative efficiencies of heating surfaces as regards heat transmission showed the water tube boiler to be 1.15 times as efficient as the fire tube boiler.

It is concluded that capital expended in ample heating surface in the cane sugar industry will always be a profitable investment and that multiple crushed bagasse is equal in fuel value to bagasse not so treated. Further data are given showing the heat used by an entire plant. Heat balances constructed on the basis of such data for two factories of high and average efficiency show that under such circumstances the second factory might operate without extra fuel while the first would have a great surplus for other uses.

It is concluded "that the heat balance of a cane sugar factory will depend on a multitude of factors so that an analysis is required of each individual factory. The factors without the control of the factory executive are: (1) Fiber in cane, controlling the steam available; (2) sugar in cane, controlling the amount of evaporation to be done at single effect and at multiple effect. The factor under the control of the factory executive is efficiency of the factory, including therein heating surface in boilers and control of the combustion, protection of hot surfaces, sufficient heating surface in evaporators to obtain not less than 65° Brix in sirup, and arrangement of plant to allow of the use of extra steam and of multiple heating."

Central station power for farmers, D. R. PALMQUIST (*Sci. Amer., 109 (1913), No. 22, pp. 405, 417, figs. 3*).—This article gives "specific data and information" as to the cost on farms of using electric power from central stations.

Ruralizing electricity, J. E. DAVIDSON (*Jour. Electricity*, 31 (1913), No. 16, pp. 339-344, figs. 4).—This article deals with the more important uses of electricity in rural districts, principally under conditions encountered in the Northwestern States and from the viewpoint of the central station manager.

Harvesting ice with central-station energy (*Elect. World*, 63 (1914), No. 2, p. 96, figs. 3).—The successful use of central-station electrical energy at 8 cts. per kilowatt hour for ice harvesting in place of a portable engine and boiler is reported. The equipment consisted of an induction motor, countershaft, transformers, meter, and switch. In making the application the engine connecting rod was unbolted from the crank shaft and the flywheel was belted directly to the motor-driven countershaft on the truck, the rest of the hoisting mechanism remaining unchanged.

Farm machinery laboratory manual, D. SCOATES (*Agricultural College, Miss.*, 1913, pp. 48).—This manual contains a list of exercises for the student of farm machinery. These consist of examining the different farm machines with regard to manufacture, construction, and operation.

Agricultural machines and implements, J. HAGMANN (*Jahresber. Landw.* 27 (1912), pp. 466-505, figs. 29).—This article describes and illustrates a number of what are considered the more recent and efficient developments in agricultural implements and machinery, including power plows, tractors, harrows, manure spreaders, drags, drills, cultivating machinery, mechanical irrigation plants, hay and grain mowers and harvesters, threshing machinery, presses, grain sorters, cleaners and dryers, grinding mills, dairy apparatus, power apparatus, small belt driven machines, and lubricators.

Solving the fuel problem for the motor truck, H. W. SLAUSON (*Sci. Amer. Sup.*, 76 (1913), No. 1975, pp. 292-294, figs. 5).—The author deals with the characteristics of kerosene as a fuel for internal combustion engines, and describes and illustrates several devices for carbureting kerosene fuel, especially in motor truck engines.

Some experiments with steam threshing machinery at Cawnpore, B. C. BURT (*Agr. Jour. India*, 8 (1913), No. 4, pp. 347-354, pl. 1).—Experiments with animal and internal combustion power for threshing are said to have been unsatisfactory, while by the use of a small portable steam engine fairly good results were obtained. The inexperience of the labor force appeared to be the greatest handicap in all the experiments, but it is believed that steam threshing is now a practical proposition in that locality.

Farm building construction, L. J. SMITH (*Canad. Thresherman and Farmer*, 18 (1913), Nos. 1, pp. 10, 64, figs. 2; 2, pp. 66, 69, 70, figs. 4; 4, pp. 80, 82, 83, figs. 5; 5, pp. 22, 24, 62, figs. 5).—This article presents both by drawings and popular discussion the principles of construction of the various types of farm buildings, with particular reference to their adaptability to the conditions of the Northwest. The principal subjects dealt with are locating and laying out buildings, building foundations, stone walls, framing, and roofs.

[**Farm building, planning, and construction**] (*Illus. Landw. Ztg.*, 33 (1913), No. 87, pp. 779-792, figs. 46).—Special articles contained in this periodical dealing with agricultural buildings are as follows: *Agricultural Building Construction*, by D. Schucht (pp. 779, 780); *Building Material*, by R. Preuss (pp. 780, 783), which discusses the use of brick, stone, cement, and wood in the construction of agricultural buildings; *Newer Plans for Farm Buildings*, by E. Kühn (pp. 783-785), which describes and gives diagrammatic illustrations of more recent developments in German farm building construction; *New Swabian Farm Houses*, by C. Friz (pp. 785, 786); *Farmyard Arrangement*, by Thaler (pp. 786, 787); *Sanitary Stall Construction*, by P. Sieck (pp. 787-789), which gives descriptions and diagrammatic illustrations of recent developments in

German stock barns; *Economical Buildings*, by F. JUMMERSPACH (pp. 789, 790), which gives plans and sections of buildings; and *Laborers' Dwellings*, by F. WAGNER (pp. 790-792), which describes, illustrates, and gives plans and brief specifications for dwellings fitted for farm laborers.

Cheaply constructed tanks, L. K. WARD (*Jour. Dept. Agr. So. Aust.*, 17 (1913), No. 4, pp. 453-455, figs. 4).—Small cement and rubble and mud-lined tanks are diagrammatically illustrated and their construction briefly described.

The construction of dipping tanks for cattle (*Rhodesia Agr. Jour.*, 11 (1913), No. 2, pp. 196-206, pls. 3).—Detailed plans, specifications, and suggestions to "serve as a model of general applicability" in the construction of dipping tanks are given, followed by hints on dipping.

Modern practice in heating and ventilation, X, XII, A. G. KING (*Dom. Engin.*, 65 (1913), No. 11, pp. 341-343, figs. 7; 66 (1914), No. 1, pp. 6-8, figs. 4).—The first of these articles describes and gives suggestions for the actual installation of the single main or one-pipe system of hot water heating with diagrammatic illustrations. The second gives information regarding forced circulation of hot water in domestic heating systems, and describes lay-out methods and methods of figuring connections.

Sizes of pipe for gravity hot water [heating] systems, M. S. COOLEY (*Dom. Engin.*, 66 (1914), No. 1, pp. 2-5, fig. 1).—This article gives a chart for determining the proper sizes of piping for a hot water heating system and describes the method by which it was devised and its practical application, including formulas for use under various conditions.

Good and bad plumbing installations (*Dom. Engin.*, 66 (1914), No. 2, pp. 30-32, figs. 12).—Up-to-date household sanitary fittings are described and illustrated, and good and poor methods of installation discussed.

RURAL ECONOMICS.

Rural versus urban: Their conflict and its causes, J. W. BOOKWALTER (*New York*, 1911, pp. VIII+292).—The author maintains that through lack of coordination in the growth and expansion of agriculture and other industries in the United States there has been a wide disparity in the distribution of the total created wealth between the rural and urban population. It is claimed that if the Government, by a judicious distribution of public lands, had maintained a proper coordination there would yet remain a large and untouched domain of fertile lands which would guarantee peaceful thrift and industry throughout the nation.

The church and the rural community, W. H. WILSON (*Amer. Jour. Sociol.*, 16 (1911), No. 5, pp. 668-693).—According to the author there have been three phases of economic experiences in the development of American agriculture, the pioneer, the exploiter, and the husbandman. Each has had its influence on the country church.

As a few striking exceptions to this general statement, he mentions the Pennsylvania Dutch and Quaker communities. These have been an economic success from their establishment, have eliminated pauperism, and maintained their social organizations.

The reason given for the decadence of most of the country churches is the wastefulness in the past of the American rural and ecclesiastical economy. In the future, he believes that the church must recognize that religion is the result not only of personal but of social experience. A number of successful rural churches are cited and it is maintained that success depends upon church unity and the economic prosperity of the farmer. The ministry of the country church should be trained with these two facts in mind.

The rural housing question, T. B. PHILLIPS (*Jour. Roy. Soc. Arts*, 62 (1914), No. 3197, pp. 324-335, figs. 4).—The housing problem in England arises from two factors, a slight increase in agricultural population and a marked increase in the number of persons working in towns but living in the country and in many cases taking up the houses formerly occupied by agricultural laborers. The remedies suggested are increased wages so that the agricultural laborer could pay a remunerative rent, cheapening the cost of living, and state aid. The first is considered the best means of improvement.

England's foundation: Agriculture and the State, J. S. MILLS (*London*, 1911, pp. V+93).—The author discusses the changes that were predicted would follow by a repeal of the Corn Laws, the decline in agricultural production, and the influence of these two factors upon the social and physical welfare of the people and the available food supply in time of war. Among his conclusions are the following: The first duty and function of any social community is to be able to feed its members. A State or nation that has to buy its food from outside its borders must always have a far lower security for its welfare and independent existence than an organization which is self-sufficient in the elements of life.

How shall farmers organize? W. R. CAMP (*North Carolina Sta. Bul.* 225 (1914), pp. 3-17).—This bulletin discusses the methods that may be used to get people together to incorporate a cooperative association and to petition for a certificate of incorporation, outlines the by-laws for a cooperative purchase and sales society, shows the difference between a cooperative society and the ordinary business corporation, and gives lists of the publications relating to farm credit, marketing, and business organization and of farmers' organizations in North Carolina.

Report of the agricultural credit commission of the Province of Saskatchewan, 1913 (*Regina: Govt.*, 1913, pp. 224+III, pl. 1).—This report outlines the methods used in European countries in supplying agricultural credit, describes the agricultural and economic conditions in the Province, and gives recommendations for solving the agricultural credit situation. Among the recommendations are that the liability of the members of local credit associations be limited to an amount not more than 50 per cent greater than the amount of their loans, all mortgage loans to be issued on the amortization basis to cover a period of not less than 15 nor more than 35 years, the rate of interest be limited to the cost to the association of the money itself and the necessary running expenses, loans be limited to 40 per cent of the value of the property to be mortgaged, and that an association shall consist of at least 10 members with a combined mortgage loan of at least \$5,000, the local associations to be united into a central association known as the Saskatchewan Cooperative Farm Mortgage Association.

Report of the work of mutual agricultural credit banks and the results obtained in 1912, RAYNAUD (*Bul. Mens. Off. Renseig. Agr.* [Paris], 13 (1914), No. 1, pp. 11-17).—This report gives for the 98 regional banks that received advances from the State the amount of advances granted and repayments made for 1912 by geographic divisions, and for France as a whole the operation of the regional and local banks and cooperative societies for the transformation and sale of agricultural products for 1911-12.

The garden to table express, C. C. MILLER (*Business America*, 15 (1914), No. 2, pp. 160-163).—The author discusses the marketing conditions in New York City and the proposed municipal wholesale markets. The new market system will have a market in each borough, located if possible on a water front so as to have both water and railroad connections. It will have a daily auction

sale to fix prices and a daily bulletin showing the quantity and prices of supplies in the market.

The drift to the city in relation to the rural problem, J. M. GILLETTE (*Amer. Jour. Sociol.*, 16 (1911), No. 5, pp. 645-667).—The author concludes that the increase in rural population is in reverse and that in urban population is in direct proportion to the degree of industrialization. He considers that the increase in urban population is due primarily to immigration, that migration from rural districts is of secondary importance, and that the birth rate is approximately the same in the urban as in the rural districts. Although the birth rate for those of the same nativity is higher in rural districts than in urban, the preponderance of foreigners in cities tends to equalize the rate.

The most serious effect of migration from rural communities is the loss of leadership. The author would check this cityward movement by improving the home and social conditions and reorganizing the rural schools.

The movement of rural population in Illinois, H. E. HOAGLAND (*Jour. Polit. Econ.*, 20 (1912), No. 9, pp. 913-927).—According to the author the poverty of rural social life has not been the cause of rural depopulation, since the regions with a decrease in population are not found to be the ones where the farmer's life is duller or more monotonous than those in which the rural population has increased. The exodus from rural communities has been fully as active since the introduction of rural free delivery, the telephone, and better roads as before. The increased use of machinery, increase in the relative number of horses, and in saving of time by use of the telephone and by improving the roads have done much toward increasing the efficiency of the farmers so that it takes less of them to produce a given quantity. These same factors have influenced the changes in the small rural villages or towns since they have made the larger town more accessible and have taken away the necessity of frequent trips to the village.

The migration of people within France and from foreign countries and between the urban and rural districts, É. PAYEN (*Écon. Franç.*, 42 (1914), I, No. 7, pp. 227-229).—This article calls attention to the fact that the number of foreigners in France has increased from 106 per 10,000 inhabitants in 1851 to 286 in 1911. It also shows that the rural population has decreased from 26,650,446 in 1846 to 22,093,318 in 1911, while the urban population has increased from 8,751,315 in 1846 to 17,508,940 in 1911. Attention is called to the localities with the more marked changes.

["World" increase in population and agricultural production], N. C. MURRAY (*Amer. Econ. Rev.*, 3 (1913), No. 1, Sup., pp. 29-31).—The author points out that the population of the civilized world, excluding China, has been increasing at a rate slightly more than 1 per cent a year, the production of wheat, corn, oats, and barley more than 2 per cent a year, of potatoes more than 3 per cent, and of sugar nearly 4 per cent. The supply of animal products has also kept pace with the population. Although there has been a decline in the exports of agricultural products from the United States, the quantity remaining for home consumption has increased faster than the population.

Index number as expressing the fluctuation of agricultural production in France, E. GAIN (*Rev. Gén. Sci.*, 25 (1914), No. 2, pp. 47-49).—The author, by dividing the difference between the maximum and minimum by the average, obtains the index number of the fluctuation in cultivated area, total production, total value and value per quintal, and average yield per hectare for the principal crops for 1901-1910. He gives similar index numbers for the fluctuation in the monthly prices for a number of crops and of meat for 1891-1910. This article is devoted to a description of his method and the results obtained.

Statistics of prices (*Viertelj. Statist. Deut. Reichs*, 22 (1913), No. 3, pp. 44-55).—This report gives the monthly prices for meat animals and the weekly prices for rye and wheat at the principal large markets of Germany for 1908-1912.

Acreage, harvest, and manufacture of tobacco in Germany (*Viertelj. Statist. Deut. Reichs*, 22 (1913), No. 3, pp. 109-125).—Data are given for 1912 showing by Provinces the number of planters, area planted, amount harvested and value, number of manufacturing establishments, and other data relating to the manufacture of tobacco.

Agricultural statistics of Austria for 1912 (*Statist. Jahrb. K. K. Ackerb. Min.* [Vienna], 1912, pp. IV+300).—This is the annual report of the Minister of Agriculture, and gives data showing the area cultivated, in meadow, in garden, and in pasture, and the production, average yield, and prices for all farm crops for 1912 by minor geographic divisions.

Yearly statement regarding dairying in Austria for 1911 (*Jahresber. Stand Milchw.* [Austria], 1911, pp. 270).—This report gives by minor subdivisions the kind of establishments, membership, milk received, butter and cheese made, and other data regarding dairying in Austria.

Russia, D. M. WALLACE (*London, Paris, New York, and Melbourne*, 1905, vols. 1, pp. XVI+456, pls. 2; 2, pp. XII+487, pl. 1).—The author of these volumes gives a vivid and detailed description of conditions in Russia. Among the chapters are the following that relate to agriculture: The peasantry of the North; the mir, or village community; the pastoral tribes of the steppe; landed proprietors of the old school; the emancipation of the serfs; and the emancipated peasantry.

Agricultural statistics of Roumania (*Min. Agr., Statist. Agr. Românici*, 1913, pt. 1, pp. 8).—This is the annual statement giving the area devoted to cereal, fiber, leguminous, and industrial plants, gardens, forage, and vineyards for the crop year 1912-13 by geographic divisions, and comparative data for Roumania as a whole for 1908-1913.

Agriculture in Hausa Land, northern Nigeria, P. H. LAMB (*Bul. Imp. Inst.* [So. Kensington], 11 (1913), No. 4, pp. 626-634).—This article describes the methods of cultivation, the natural fertility of the soil, and the possibilities of future development of the agriculture.

[Agriculture in Japan], Y. TAKENOB and K. KAWAKAMI (*Japan Year Book*, 1913, pp. 155-177).—This chapter of the yearbook is devoted to the various economic factors in agriculture, such as arable land, farming population, increase of productive power, condition of tenant farmers, animal labor, farmers' debts, irrigation and drainage, area, production, and trade in staple farm products, sericulture, stock farming, poultry, and dairy and meat preserving.

Season and crop report of Bengal for the year 1912-13, J. R. BLACKWOOD (*Dept. Agr. Bengal, Season and Crop Rpt. 1912-13*, pp. 46).—This report gives statistical data, showing by districts the rainfall, classification of agricultural lands, area under crop, yield per acre of the principal farm crops expressed in percentage of the normal yield, harvest prices, and number of live stock.

Variations in Indian price levels (*Calcutta: Com. Intel. Dept.*, 1913, pp. 16, pls. 5).—Index numbers are shown for the prices of the principal vegetable and animal foods, sugar, tea, coffee, textiles, hides, and tallow for 1861-1912.

Farm management (*Amer. Econ. Rev.*, 3 (1913), No. 1, Sup., pp. 96-113).—This article consists of a round table discussion of the various phases of farm management by H. C. Taylor, T. N. Carver, C. K. Graham, J. A. Valentine, R. Hittinger, W. H. Bowker, and W. O. Hedrick. The principal phases emphasized are farm accounting, the use of machinery and hand labor, and the relationship of the various factors in agricultural production.

AGRICULTURAL EDUCATION.

Agricultural education and its relation to rural sociology, A. F. WOODS (*Amer. Jour. Sociol.*, 17 (1912), No. 5, pp. 659-668).—The author discusses the rural school, holding that "faulty education and educational methods are among the more fundamental of the limiting factors to proper social development;" economic conditions, which necessitate the development of better community life in rural districts generally; and educational methods, including as most effective the movable schools, short courses, institutes, the farmers' club, the grange and other similar organizations, and local demonstration farms. The work of the last-named "has been carried out with skill and the results have been clear, but the educational effect produced has been as a rule unsatisfactory." The average man who came to view the demonstration farm, while fully impressed with the importance of the work, went away with the feeling that it was something beyond his capabilities." Hence, less attention has been given to state demonstration farms and more to directing the individual farmer in reorganizing his own farm. He is shown how cooperative marketing adds greatly to the profits. This leads to cooperative buying and other cooperative efforts.

State and national aid in the improvement of public roads, drainage, the dissemination of agricultural information, and the improvement of the school system, especially along industrial lines, is regarded as a great stimulus to improvement in many rural communities. A brief survey is given of the results of state aid for instruction in agriculture in the high schools of Minnesota. The author emphasizes the cooperation of all educational agencies, both state and national, as a means of accomplishing a socialization of country life according to the best American ideals.

Sequence of science and agriculture in the high school, J. MAIN (*School Sci. and Math.*, 13 (1913), No. 8, pp. 695-700).—In this consideration of the problem of what the high school sciences shall be, the order in which they shall be given, and how they shall be affected by the introduction of industrial subjects such as agriculture, the author thinks that the final analysis of accurate gradation and sequence of all rational school subjects will probably be found to conform to muscular development. In agriculture all the subjects involve the use of both large and small muscles. Subjects demanding more use of the finer muscles come later in the course than those involving more use of the coarser. Those requiring skill and accuracy of the larger muscles may often have an early or late treatment or both. He suggests a sequence of agricultural subjects according to this test of motor adjustment.

A course in the natural history of the farm, J. G. NEEDHAM (*Nature-Study Rev.*, 9 (1913), No. 6, pp. 170-174, fig. 1).—In view of a lack of appreciation in his students of any relation between their previous nature work and the studies in pure science which occupy chiefly the earlier years of their college course, the author began in the spring of 1913 the preparation of a course on the natural history of the farm which he gave in the fall to a class of 400 freshmen then entering the New York State College of Agriculture. It consisted of one lecture and one field trip a week and proved very satisfactory. The field work is described.

Field work records, J. G. NEEDHAM (*Nature-Study Rev.*, 9 (1913), No. 7, pp. 203-207).—The author requires 4 different sorts of field work records according to the nature of the work involved, viz, drawings and structural diagrams, maps, tables, and annotated lists, each of which is briefly described. He points out that a record of field work facilitates the accumulation and com-

parison of data, concentrates attention on specific points, gives purpose to observation, and insures results.

College work in plant pathology, F. H. BLODGETT (*Plant World*, 16 (1913), No. 11, pp. 304-314).—In this discussion of college work in plant pathology the author concludes that such work may be given advantageously as a part of the regular work in horticulture, when it would naturally be the concluding course of the group taken and occupy a part or all of the senior year. The subject matter should be so chosen as to show the most serious diseases of important crop plants with due consideration for as wide a range of types of parasitic fungi as practicable. The student on graduation should be able to give actual help in his community in recognizing and controlling the common diseases of crops.

Suggestions for the development of higher horticultural institutions [in Germany], K. HEICKE (*Möllers Deut. Gärt. Ztg.*, 28 (1913), No. 43, pp. 511-513).—The author discusses a suggested reorganization of the higher horticultural institutions in Germany, viz, at Dahlem, Geisenheim, and Proskau, whereby each institution would specialize in one of the principal branches of horticulture instead of competing with each other in covering the whole field of horticulture as at present. Each institution would still provide a preliminary course in the fundamentals of horticulture so that students could readily change from one institution to another for specialization.

The Wurttemberg Cheese School and Experiment Station (*Die Württembergische Käseerei-Versuchs- und Lehranstalt zu Wangen im Allgäu. Bergedorf* [1913], pp. 35, figs. 17).—An account of the equipment, arrangement, and work of the Wurttemberg Cheese School and Experiment Station.

The modern English farmer's wife, MARY L. MOORE (*Breeder's Gaz.*, 64 (1913), No. 25, pp. 1239, 1242c, figs. 2).—In addition to describing the general conditions of farm life from the woman's standpoint, mention is made of the rapid growth of educational work in home economics and the great importance of this movement to the housekeeper.

A course in general science for high schools, to be used as an introduction to agriculture, domestic science, and other science courses, W. L. EIKENBERRY (*School Sci. and Math.*, 14 (1914), No. 2, pp. 186, 188).—An outline is given of a course in general science as an introduction to agriculture, domestic science, and other science courses arranged under the following principal topics: The air and our relation to it, water and its uses, work and energy, the earth's crust, and life on the earth.

One year's course in secondary agriculture, A. W. NOLAN (*School Sci. and Math.*, 14 (1914), No. 2, pp. 143-146).—The author gives a detailed outline of a secondary course in agriculture comprising studies of matured plants, animals, farm business and life, machinery, soils, and conditions of plant growth.

The leaf-portfolio as an aid in tree study, ANNA B. COMSTOCK (*Nature-Study Rev.*, 9 (1913), No. 7, pp. 197-202, figs. 4).—The author describes several ways of making leaf portfolios, in any of which it is essential that accuracy be observed in determining the trees so as to label the leaves properly, and that the collection be made as complete as possible. Such a collection serves to teach the pupil about the objects collected, remains as a reference to refresh the memory, and may also be beautiful as well as interesting.

School gardens in Idaho, MAMIE L. POLLARD (*Nature-Study Rev.*, 9 (1913), No. 7, pp. 207-213, figs. 4).—The school garden work at the Lewiston State Normal School is described. This is a part of the department of nature study in all grades of the training school above the first grade, unifying into a central scheme. The aims for grades 2 and 3 are to educate children in the proper use of garden tools, to keep the garden weedless and well cultivated,

and to identify readily the seeds and plants of 4 or 5 common vegetables; for grades 4, 5, and 6 to ascertain the value of manual dexterity and the money saving effected by owning a garden; and for grades 7 and 8 to note the reasons for various processes. Grades 4 to 8, inclusive, have individual gardens. The problem of summer care of gardens is solved by the summer school continuing until August 1 and having a man in charge thereafter until the autumn session.

The North Dakota pork production contest, V. STEPHENS (*Farmer*, 32 (1914), No. 8, p. 271, figs. 3).—An account is given of a competition entered into by 300 farm boys and girls between the ages of 10 and 18, to secure the largest production of pork at the lowest feed cost a pound in the shortest period of time. The contest extended from March 10 to November 20 and was under the direction of the Better Farming Association. The 29 prizes consisted of \$340 offered by live stock commission firms, pure-bred hogs by individuals interested in hog raising, and several tool chests by a hardware firm. The 16-year-old winner of the first prize made a profit of \$91.06 on his litter of 14 pigs in 203 days with pork at 6 cts. a pound, producing 2,903 lbs. pork at a feed cost of 2.8 cents a pound. The second prize was won by a 12-year-old girl who sold her litter of 8 pigs a month after the close of the contest for 7 cts. a pound, and produced 2,098 pounds of pork in 218 days at a feed cost of 1.7 cents a pound.

MISCELLANEOUS.

Annual Report of Hawaii Station, 1913 (*Hawaii Sta. Rpt. 1913*, pp. 53, pls. 3).—This contains the organization list, a summary by the special agent in charge as to the investigations of the year, and reports of the entomologist, horticulturist, assistant horticulturist, chemist (including analyses of lava), agronomist, assistant agronomist, and superintendent of the substations. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Twenty-sixth Annual Report of Louisiana Stations, 1913 (*Louisiana Stas. Rpt. 1913*, pp. 54).—This contains the organization list, a report by the director discussing the functions and work of the stations, an account of their progress, including brief departmental reports, and a financial statement as to the federal funds for the fiscal year ended June 30, 1913, and as to the state funds for the fiscal year ended November 30, 1913.

Twenty-sixth Annual Report of New York Cornell Station, 1913 (*New York Cornell Sta. Rpt. 1913*, pp. CXLIII+954, pls. 48, figs. 212).—This contains the organization list, reports of the director of the station and heads of departments, a financial statement as to the federal funds for the fiscal year ended June 30, 1913, and as to the state funds for the fiscal year ended September 30, 1913, and reprints of Bulletins 321-333, Memoirs 1 and 2, and Circulars 13-20, all of which have been previously noted, and of Bulletins 334 and 335 abstracted elsewhere in this issue.

Director's report for 1913, W. H. JORDAN (*New York State Sta. Bul. 372* (1913), pp. 549-574).—This contains the organization list and a review of the work and publications of the station during the year.

Proceedings of the fourth general assembly (*Inst. Internat. Agr. [Rome], Actes 4. Assemblée Gén., 1913*, pp. VII+574).—This volume contains the reports to the general assembly of the International Institute of Agriculture concerning statistics of agriculture, live stock, and commerce, plant diseases, adulteration of seeds, agricultural meteorology, protection of birds, statistics of fertilizers, dry farming, farm accounts, statistics of cooperation, and insurance against hail. See also a previous note (E. S. R., 29, p. 1).

NOTES.

California University.—The university granted about 900 degrees at its recent commencement. A number of summer expeditions of agricultural students have been arranged to study soils, agronomy, citriculture, animal industry, etc. About 80 agricultural clubs have been organized in high schools by the extension division assisted by the agricultural club of the college of agriculture. Seven counties have now organized farm bureaus for conducting extension work.

Connecticut Stations.—The stations are planning a corn survey of the State, the idea being to ascertain what varieties are being raised with the best results in different sections, to compare these varieties by growing them in the northern and southern sections, and to inaugurate the work of improvement by selection. It is thought possible that a portion of this work may be entrusted to certain farmers who will grow seed for sale in the State.

Oregon College and Station.—Beginning with the ensuing academic year, the entrance requirements for the degree courses will be so increased as to render eligible only students who have taken three years of high school work and have a minimum of 12 credit units. The following year a further increase to 4 years of high school work or its equivalent will be made. It is expected that candidates who have not had these advantages will be enabled to qualify through the newly established vocational courses. These courses will extend over one year, providing work in agriculture, domestic science, and farm shop work.

Eleven counties of the State are now cooperating in the county demonstration work. Particular attention is being given to such phases as the introduction of clover crops and alfalfa for fertility maintenance, the building of silos, combating fire blight, and the testing of dairy herds through associations of dairymen.

V. I. Safro, research assistant in entomology in the station, has resigned to take effect July 1.

Pennsylvania College.—A rest room in the local national bank is being fitted up for use by farmers. A member of the senior class of the college is providing a series of charts for use in the room.

Porto Rico Federal Station.—C. N. Ageton, assistant chemist, has resigned to accept a position as chemist for the Central Experiment Station in Cuba.

Clemson College.—An allotment of \$300 has been made by the trustees for a study of the limestone and marl deposits of the State and their value for agricultural purposes. The work will be in charge of F. H. H. Calhoun, professor of geology and mineralogy.

Tennessee University and Station.—The East Tennessee Farmers' Convention held its forty-first annual meeting on the station farm May 19-21 with an attendance of approximately 2,500.

An agricultural train is to be fitted up to traverse the State during July, August, and September.

The following changes in the station staff occurred March 1. E. C. Cotton, assistant entomologist, resigned to carry on a commercial orchard in Ohio. G. M. Bentley, assistant zoologist and entomologist, has been appointed entomologist, and H. R. Watts, assistant entomologist.

<i>Arctia carya</i> , notes	54, 855	flour, Kans.	555
<i>Argesalis</i> n. sp., description	60	<i>Aspergillus</i> —	
Arginin, distribution in plants	129	<i>niger</i> , amygdalin diastases in	241
Arithmetic, agricultural, text-book	795	<i>niger</i> as affected by chemicals	241, 630
Arizona University and Station, notes	796	<i>niger</i> as affected by metals	824
Arkansas University and Station, notes	95, 796	<i>niger</i> , assimilation of zinc by	523
<i>Armillaria mellea</i> —		<i>niger</i> , enzymes in	805
description	151	<i>niger</i> , metabolism in	727
treatment	649	<i>niger</i> , mutations in	630
Army—		<i>niger</i> , notes	450
rations, field service, scale for	169	<i>niger</i> , utilization of phytin by	805
worm, fall, notes	252, 656	<i>oryza</i> , koji acid from	202
worm, fall, notes, Mass.	154	spp., cleavage of methyl glucosid by	11
worm, remedies	456	Asphalt paving cements and road binders	290
<i>Arrhenatherum elatius</i> , seeding on ranges,		<i>Aspidiotus</i> —	
U.S.D.A.	35	<i>destructor</i> affecting bananas	157
Arrowhead tubers, sugar in	63, 502	<i>perniciosis</i> . (See San José scale.)	
Arrowroot—		Aspidistra, leaf spot disease of	448
bagasse, analyses	565	Association of—	
insects affecting	752	American Agricultural Colleges and Ex-	
varieties	434	periment Stations	399
Arsenic—		American Dairy, Food, and Drug Offi-	
absorption by green plants	130	cialists	862
acid, reduction to arsenious acid,		Austrian Experiment Stations	599
U.S.D.A.	801	Feed Control Officials	466
as a normal element of soils	321	Official Agricultural Chemists, U.S.D.A.	317
determination in dipping agents, U.S.		<i>Astrelba pectinata</i> , culture experiments	632
D.A.	801	Athletes, training	465
determination in fungicides and insecti-		Atmosphere, radio-active products in	619
cides	416	Atmospheric—	
effect on nitrogen transformation in		impurities, effect on vegetation	32
soils	423, 424	pressure. (See Barometric pressure.)	
in soils	423	temperature. (See Temperature.)	
Arsenical dips, notes	778	<i>Atractonotus mali</i> , notes	53
Arsenicals, use for plant protection	236	<i>Atriplex</i> —	
Arsenobenzol, use against equine influenza	385	<i>leptocarpa canescens</i> , culture experiments	632
		<i>semibaccata</i> , seeding on ranges, U.S.D.A.	35

Vocational education—		methods of analysis.....	13
federal commission on.....	398	movement in plants.....	202
in Massachusetts.....	195	pollution, effect on fish.....	319
Volcanic dust, precipitation from the air....	417	power laws in Nebraska.....	486
Voles, destruction.....	545	powers, pipe lines for.....	188
Wages, farm, in France.....	91	purification.....	318
Waiters, supervision of health of.....	863	purification, N.Dak.....	620
Walnut—		purification and sewage disposal, treatise..	511
aphis, remedies, Cal.....	345	purifiers, ozone, description.....	789
blight, treatment, Cal.....	345	rain. (See Rain.)	
Walnuts—		requirements of crops, U.S.D.A.....	34
black, development of fat in.....	411	resources of California.....	599
new form, description.....	644	resources of Sulphur Spring Valley, Ari-	
parthenogenesis in.....	544	zona.....	18
Wapato as a duck food, U.S.D.A.....	545	resources of western Australia, develop-	
Washington—		ment.....	587
College, notes.....	96, 497	rôle in macadam road construction.....	788
Station, notes.....	497	rôle in sugar hydrolysis.....	411
Wasps, wood, studies.....	59	Salton, bacteria in.....	431
Water—		solids and organic matter in, N.Dak.....	620
alkali, effect on dairy cows, S.Dak.....	775	sterilization by ultraviolet rays.....	419, 816
alkaline, effect on lead.....	511	supply, contamination, N.Dak.....	620
analyses, N.Dak.....	620	supply for country homes, U.S.D.A.....	690
analysis, treatise.....	12	supply for farms.....	89, 294
bacterial content as affected by storage..	713	supply in rural districts.....	390
brackish, irrigation with.....	886	supply, lead poisoning through.....	418
composition and properties.....	620	supply, mycology of.....	418
conduits, designing.....	887	supply of Boxelder and Tooele Counties,	
cress, polluted, typhoid epidemic from..	64	Utah.....	18
determination in butter.....	113	supply of British Columbia.....	287
determination in corn.....	506	supply of Florida.....	17, 119
determination in flour and meal, U.S.D.A..	506	supply of Ohio River Basin.....	18
determination in foods.....	505	supply of South Atlantic and eastern Gulf	
determination in plant substances.....	507	of Mexico drainage basins.....	17
distilled, effect on lupines.....	825	supply of South Australia.....	211

Water—Continued.	Page.	Wheat—Continued.	Page.
supply of southern California.....	688	composition as affected by environment, U.S.D.A.....	449
supply of Victoria.....	887	composition at different stages.....	137
supply on railway trains.....	863	continuous culture.....	124
supply, pipe lines for.....	188	culture, U.S.D.A.....	444
supply, relation to typhoid fever.....	319	culture contents in western Australian schools.....	744
surfaces, evaporation from.....	118, 713	culture experiments, 33, 134, 525, 531, 632	
system, pneumatic, notes.....	499	culture experiments, Wis.....	141
tank and silo, combined, construction...	489	culture in Illinois.....	411
underground, in South Australia.....	211	culture in India.....	639
underground, pollution through rock fis- sures.....	19	culture in Nebraska.....	841
Watering devices for live stock.....	389	culture in Wisconsin, Wis.....	141
Watermelon blossom-end blight, notes.....	537	culture on moorland.....	229
Waterways, artificial, frictional resistance in Colo.....	885	culture under dry farming.....	435
Wax, Grecian, analyses.....	258	diseases in Egypt.....	747
Waxes—		diseases, studies and bibliography, U.S.D.A.....	846
of Dutch East Indies.....	697	distance experiments.....	732
treatise.....	310	dry-farm, chemical studies, Utah.....	199
Weather—		durum, milling and baking tests, N.Dak.....	662
forecasting, notes.....	510, 712, 713	dwarf varieties, stability.....	411
of Upper San Joaquin watershed, U.S.D.A.....	713	fertilizer experiments.....	125, 229, 235, 335, 531, 627, 821
phenomena, notes.....	416	fertilizer experiments, N.J.....	325, 326
relation to wheat stalk disease.....	541	fixity of races in.....	341
types of in United States.....	814	flour. (See Flour.)	
Weed seeds. (See Seeds, weed.)		foot or stalk disease, notes.....	242, 243, 349, 541
Weeds—		Fusarium diseases in Bavaria.....	748
destruction.....	826, 837	German and foreign, bread-making quali- ties.....	257
destruction in lawns, Mass.....	146	germinated, baking quality, Kans.....	555
destruction in wheat fields.....	441	germination as affected by fungicides and insecticides.....	242, 837
notes.....	632	germination as affected by hot-water treatment.....	419
of arable land.....	399	germination as affected by temperature..	531
(See also specific plants.)		germination in mercury vapor light.....	827
Weight and measures law in Nevada, Nev..	165	germination tests.....	236, 837
Weights, conversion into metric system.....	697	grading, N.Dak.....	663
Well equipment, notes.....	385	grass, slender, seeding on ranges, U.S.D.A.	35
Wells and ground water, text-book.....	620	growth as affected by electricity.....	827
West Virginia—		growth as affected by manganese, U.S.D.A.....	823
Station, bulletins of.....	94	hard red spring, milling tests, N.Dak.....	662
Station, report.....	94	hybrid, notes.....	140
University and Station, notes.....	300, 798	hybridization experiments.....	733
Western twig borer, notes.....	255	irrigated, chemical studies, Utah.....	460
Wheat—		irrigation experiments, U.S.D.A.....	35
analyses.....	565	kernel, crease of, N.Dak.....	666
analyses, U.S.D.A.....	434	loose smut, notes.....	448
and its milling products, composition....	257	louse, notes.....	658
and rye, fertile hybrid of.....	341	Marquis, history and culture, Minn.....	738
as affected by radio-activity.....	224	Marquis, milling quality, Minn.....	760
as affected by spacing in breeding plats..	633	Marquis, milling quality, N.Dak.....	666
as affected by temperature, N.Dak.....	664	meal, digestibility.....	566
baking quality as affected by storage, N.Dak.....	667	measurements.....	235
botanical notes.....	240	middlings, analyses.....	671, 868
bran, analyses.....	868	middlings, analyses, Ind.....	169
bran, analyses, Conn.State.....	868	middlings, analyses, La.....	565
bran, analyses, Ind.....	169	middlings, analyses, Mass.....	67
bran, analyses, La.....	565	middlings, analyses, N.Y.State.....	68
bran, analyses, Mass.....	67	mildew, relation to light.....	747
bran, analyses, N.Y.State.....	68	milling and baking studies, N.Dak.....	661, 663, 664, 666, 668
breeding experiments.....	331, 441, 525	milling and baking studies, Utah.....	460
breeding, selection in.....	733	nematodes affecting.....	243, 448
bug, notes.....	854		
catalytic fertilizers for.....	627		
change in weight during storage, Utah....	639		

Wheat—Continued.	Page.	Wine—Continued.	Page.
phosphorus content, N.Dak.....	362	crystalline deposits in.....	612
Portuguese varieties.....	40	diseases, examination and treatment....	712
prices of in Germany.....	896	fermentation changes in.....	612
production and consumption.....	391, 692	from American native grapes, composi- tion.....	16
products, analyses, Ind.....	169	growers' schools, instruction in.....	195
protein content, relation to soil moisture, N.Dak.....	662	making experiments.....	612
protein content, variations in.....	836	methods of analysis.....	612
puffed, analyses, Mass.....	67	orange, manufacture, Cal.....	814
puffed, analyses, N.Y.State.....	68	refermentation.....	612
Rieti hybrid of.....	531	secondary fermentations in.....	712
root development of seedlings.....	136	yeasts in.....	711, 712
rust, notes.....	845	Wireworms—	
rust resistance in.....	242	notes.....	454, 753
rust spores in seeds of.....	241	studies, S.C.....	546
screenings, analyses, N.Dak.....	671	Wisconsin University and Station, notes....	498,
screenings, digestibility.....	566		600, 699
seedling experiments.....	526	Wold grass, yields.....	134
seedling experiments, U.S.D.A.....	135	Women—	
seedlings, living and killed, respiration....	522	agricultural instruction for.....	298, 495, 793
shorts, analyses.....	671	clerks in Bank of England, free luncheons for.....	166
shorts, analyses, Ind.....	169	cooperation among.....	395
smut, cause.....	47	farm clubs for in France.....	200
smut, treatment.....	47, 242, 743	farm, publications for, U.S.D.A.....	197
soil exchange experiments, U.S.D.A.....	440	immigrant, fecundity of.....	592
sprouting, alcohol formation by.....	522	short course for in University of Missouri..	462
sprouts, digestibility.....	566	Wood—	
stalk disease, notes.....	242, 243, 349, 541	chemistry of.....	10
starch, gelatinization point.....	10	distillation in United States.....	744, 845
stinking smut, treatment.....	351	growth and structure as affected by defo- liation.....	228
stooling in.....	235	industry of Dutch East Indies.....	697
storage experiments, N.Dak.....	639	oil, Chinese, notes, N.Dak.....	616
Turkestan varieties, description.....	830	oil tree, Chinese, culture in United States..	535
varieties.....	33, 134, 229, 235, 435, 525, 531, 731	oil trees of China and Japan.....	46
varieties, Pa.....	342	preservation.....	447, 646, 647
varieties, S.Dak.....	738	preservation with fluorids.....	239
varieties, U.S.D.A.....	135, 434	preservative, siliceous, notes.....	647
varieties, Utah.....	829	preservatives containing fluorin.....	646
varieties, Wis.....	141	preserving industry in America.....	347
varieties resistant to rust.....	230, 748	residue as a feeding stuff.....	565
white-heads or take-all, notes.....	148	screws, transverse strength of.....	889
winter resistant type.....	40	structure of East Indian pines.....	46
winter, rest period in.....	732	sugar from.....	711
xenia in.....	235	transportation in French colonies.....	447
yield and quality as affected by rainfall, N.Dak.....	662	using industries in Iowa, Iowa.....	46
yield and quality, relationship.....	639	using industries in New York.....	536
yield as affected by pasturing.....	633	using industries in Ohio, Ohio.....	536
yield, relation to rainfall, U.S.D.A.....	418	using industries in South Carolina.....	536
White—		wasps, studies.....	59
ants. (See Termites.)		waste, utilization.....	711
fly diseases, Fla.....	55	(See also Lumber and Timber.)	
grubs, notes.....	454, 656	Woods—	
grubs, notes, Conn.State.....	654	American, specific gravity and weight of..	445
top, analyses.....	565	American, specimen book.....	445
Wind—		American, tyloses in, U.S.D.A.....	844
dissemination of red spider by.....	759	of United States, U.S.D.A.....	46
effect on plant life.....	30	Rocky Mountain, for telephone poles, U.S.D.A.....	843
effect on transpiration in plants.....	726	Woodworking exercises for agricultural school shops, Minn.....	94
pathological effects on plants.....	354	Woody tissues, alterations in.....	223
power, determination.....	88	Wool—	
power, use in Egypt.....	788	as affected by dips.....	584
Windbreaks, artificial, tests.....	134	black and white, nitrogen ratios in.....	707
Wine—			
acid titration, indicators in.....	413		
analyses.....	612, 712		

Wool—Continued.	Page.	Yeast—Continued.	Page.
industry in United States.....	870	dried, for horses.....	175
investigations, Okla.....	568	examination.....	669
production in Australasia.....	372	forms of in wine.....	711, 712
statistics.....	871	osmotic pressure and electrical con-	
Woolly aphis. (<i>See</i> Aphis, woolly.)		ductivity of.....	523
Work, effect on yield and fat content of milk.	475	therapeutic action in polyneuritis.....	79
Workingmen. (<i>See</i> Laborers.)		Yellow rattles as a weed on arable land.....	141
Worms, parasitic, dispersal of eggs of by flies..	658	Yorkshire fog, notes.....	434
Wormseed, notes, U.S.D.A.....	145	<i>Ypsilophus ligulellus</i> . (<i>See</i> Palmer-worm.)	
Wort, osmotic pressure and electrical con-		<i>Zanthoxylum</i> spp., notes, U.S.D.A.....	145
ductivity of.....	523	Zebias, hybridization experiments.....	270
Wurttemberg Cheese School and Experiment		Zebus—	
Station.....	898	crossing with cattle in Tunis.....	567
Wyoming Station—		digestion experiments.....	568
notes.....	700	half-bred, milk production.....	74
report.....	697	Zein, utilization.....	316
Xanthin bases, determination in cocoa, tea,		Zeitschrift für Analytische Chemie, index.....	117
and coffee.....	810	Zeilites, soil, properties of.....	23
<i>Xanthium canadense</i> , variations in.....	729	<i>Zenopsis pyrina</i> . (<i>See</i> Leopard moth.)	
<i>Xanthium</i> seed—		<i>Zicrona carulea</i> , notes.....	459
coat, investigations.....	132	Zinc—	
germination, rôle of oxygen in.....	629	arsenite as a substitute for lead arsenate.....	53
<i>Xanthogramma scutellaris</i> , notes.....	156	arsenite, tests, Mass.....	156
Xenia—		assimilation by <i>Aspergillus niger</i>	523, 630, 824
in pears.....	740	silicofluoride as a wood preservative.....	646
in wheat.....	235	sulphate, effect on plant growth.....	130
Xenoparasitism, structural relations in.....	223	sulphate, fertilizing value.....	627
<i>Xyleborus (Anisandrus) dispar</i> , notes.....	161	Zodiacal light, U.S.D.A.....	713
Yacon, culture experiments.....	640	<i>Zonocorus elegans</i> , remedies.....	54
Yams—		Zoology—	
fertilizer experiments.....	525	agricultural, text-book.....	248
insects affecting.....	546	Canadian, bibliography.....	52
varieties.....	525	economic, treatise.....	52
Yeast—		Zootechny, treatise.....	170, 174
assimilation of atmospheric nitrogen by..	629	Zygadenin—	
cleavage of methyl glucosid by.....	11	notes.....	412
combination as a feeding stuff.....	565	notes, Wyo.....	412
culture and tests.....	712	<i>Zygadenus intermedius</i> , analyses.....	412
development in various mediums.....	111	<i>Zygosaccharomyces</i> spp. in wine.....	711
dried, enzymes of.....	504	Zygotaxis, notes.....	328
		Zymin, enzymes of.....	504
